Low-Power Flash Device Handbooks Introduction

Device Handbooks contain all the information available to help designers understand and use Actel's devices. Handbook chapters are grouped into sections on the website to simplify navigation. Each chapter of the handbook can be viewed as an individual PDF file.

At the top of the handbook web page, you will see a PDF file for each product family. This file contains the complete device handbook. Please register for product updates to be notified when a section of the handbook changes.

Table 1 • Differences between Former Datasheets and Device Handbooks

Description of Change	Comparison between Handbook and Datasheet
<p>The silicon datasheet in the handbook does not contain the same chapters as the previous versions of the datasheets.</p>	<p>The former version of the silicon datasheet contained the following:</p> <ul style="list-style-type: none"> • General Description • Device Architecture • DC and Switching Characteristics • Packaging <p>The current datasheet now contains:</p> <ul style="list-style-type: none"> • Product Brief (same information as the General Description) • DC and Switching Characteristics • Packaging <p>The information previously contained in the Device Architecture chapter has been separated into individual chapters and merged with relevant application note content to provide one location for information on each architectural feature.</p> <p>The Device Architecture section still exists in the Fusion Handbook only.</p>
<p>The General Description section no longer exists in datasheets.</p>	<p>The Product Brief and the General Description consisted of basically the same information but with different titles. To eliminate the duplicated information, we changed the document name to Product Brief.</p>
<p>Change tables were carried forward through this process; they contain information from the old datasheets and the new datasheets.</p>	<p>It is important that all earlier technical changes from the datasheets are listed so customers can determine if any of the changes affect their designs. Changes are listed chronologically, with the most current at the top and the earlier changes listed below them.</p>
<p>Version numbers were restarted.</p>	<p>The version numbers were restarted when the handbooks were created. For example, a datasheet may have been v2.1 and is now v1.0. The category (i.e., advance or production) of the datasheet did not change. The only change occurred to the actual numbering of the datasheet. All version numbers are located in the footer of the page.</p>
<p>Publication date</p>	<p>The publication date indicates when the document was published and posted to the Actel website.</p>
<p>The former datasheets were two columns and the current datasheets and handbooks are formatted with one column.</p>	<p>We changed the datasheet format to accommodate the large graphics and to improve readability.</p>

Table 1 • Differences between Former Datasheets and Device Handbooks (continued)

Description of Change	Comparison between Handbook and Datasheet
<p>Each chapter within a handbook can have a different version number.</p>	<p>Each chapter in the handbook has its own version number. Since the chapters are independent documents and can be updated at different times, the version numbers for each chapter increment only when a change is made to that chapter. For example, in the ProASIC3L handbook, the DC and Switching section is Advance v0.2, the Packaging Pin Assignments section is v1.0, and the Global Resources section is v1.1. The DC and Switching section is advance because the data has not been fully characterized. The Packaging and Global Resources chapters are both production versions because the data is final. They have different version numbers because they were updated at different times.</p>
<p>Chapters can be numbered differently in each of the handbooks, but the version number for a chapter should be consistent throughout all handbooks. Chapters are also published individually without chapter numbers.</p>	<p>Chapters with shared content are reused across multiple handbooks. The number of chapters in each handbook varies depending on content, so the Pin Descriptions chapter could be chapter 7 in one handbook and chapter 9 in another. This is shown only in the combined handbook version of the document. The content within the chapters and version numbers is the same across each handbook for that chapter. If the chapter is updated, it will be reposted for all associated handbooks.</p>
<p>There are multiple versions of the I/O Structures chapter.</p>	<p>There are several major differences between the families regarding I/O structures, so the information has been grouped by similar families.</p> <p>As a result, we have multiple I/O Structures chapters to describe the features for each group of families in detail.</p>
<p>The part number of the datasheet has changed.</p>	<p>Part numbers are used internally to track documents. Each document has its own unique part number. The number after the second dash indicates the revision of the document. For example, in the part number 51700094-006-1, 51700094-006 is the part number and 1 is the revision of the document. We start with 0 for all new documents. There is a part number for the current version of the datasheet on the back page with the addresses. In addition, all chapters in the datasheet and handbooks have their own unique part numbers. When we implemented the current handbook format, existing documents were assigned new part numbers.</p>
<p>The information contained in the Core Architecture section of the silicon handbook includes information previously found in application notes.</p>	<p>The chapters in the silicon handbook combine application notes that previously had very detailed information about an architectural feature and information from the former datasheets. In addition, because the information was very similar among several of Actel's low-power flash devices, we combined the information into one document. The Supported Families tables describe which devices are supported in the document. The application notes that contained specific architecture information were combined into the handbook and many no longer exist as standalone application notes. Those that do exist in standalone version have been assigned an AC number (top right of first page) to help identify them. The AC number appears in the standalone version and in the handbook chapters where they occur.</p>

Table 1 • Differences between Former Datasheets and Device Handbooks (continued)

Description of Change	Comparison between Handbook and Datasheet	
The location of the following information has changed in the current handbook format:		
	Former Datasheet Location	Current Handbook Location
CCC/PLL Specification Table	Core Architecture	DC and Switching section > Clock Conditioning Circuits
Peak-to-Peak Jitter Waveform	Core Architecture	DC and Switching section > Clock Conditioning Circuits

Versions

Device handbook chapters may have different version numbers. Actel's goal is to provide customers with the latest information in a timely matter. As a result, the handbook chapters will be updated independently of the handbook.

Categories

In order to provide the latest information to designers, some datasheets are published before data has been fully characterized. Datasheets are designated as "Product Brief," "Advance," "Preliminary," and "Production." The definitions of these categories are as follows:

Product Brief

The product brief is a summarized version of a datasheet (advance or production) and contains general product information. This document gives an overview of specific device and family information.

Advance

This version contains initial estimated information based on simulation, other products, devices, or speed grades. This information can be used as estimates, but not for production. This label only applies to the DC and Switching Characteristics chapter of the datasheet and will only be used when the data has not been fully characterized.

Preliminary

The datasheet contains information based on simulation and/or initial characterization. The information is believed to be correct, but changes are possible.

Unmarked (production)

This version contains information that is considered to be final.

Export Administration Regulations (EAR)

The products described in this document are subject to the Export Administration Regulations (EAR). They could require an approved export license prior to export from the United States. An export includes release of product or disclosure of technology to a foreign national inside or outside the United States.

Part Number and Revision Date

Part Number 51700094-001-2

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.2)	Page
v1.1 (November 2008)	Table 1 · Differences between Former Datasheets and Device Handbooks was revised to indicate that only the Fusion Handbook retains a Device Architecture section. The information on the I/O Structures chapters was revised, as an I/O Structures chapter has been added for nano devices.	i
v1.0 (January 2008)	This document was rewritten to address the differences between the former datasheets and new device handbooks.	N/A

Section I – IGLOO nano Datasheet

IGLOO nano Low-Power Flash FPGAs with Flash*Freeze Technology

Features and Benefits

Low Power

- nanoPower Consumption—Industry's Lowest Power
- 1.2 V to 1.5 V Core Voltage Support for Low Power
- Supports Single-Voltage System Operation
- Low-Power Active FPGA Operation
- Flash*Freeze Technology Enables Ultra-Low Power Consumption while Maintaining FPGA Content
- Easy Entry to / Exit from Ultra-Low-Power Flash*Freeze Mode

Small Footprint Packages

- As Small as 3x3 mm in Size

Wide Range of Features

- 10 k to 250 k System Gates
- Up to 36 kbits of True Dual-Port SRAM
- Up to 71 User I/Os

Reprogrammable Flash Technology

- 130-nm, 7-Layer Metal, Flash-Based CMOS Process
- Live-at-Power-Up (LAPU) Level 0 Support
- Single-Chip Solution
- Retains Programmed Design When Powered Off

In-System Programming (ISP) and Security

- Secure ISP Using On-Chip 128-Bit Advanced Encryption Standard (AES) Decryption via JTAG (IEEE 1532-compliant)
- FlashLock[®] to Secure FPGA Contents

High-Performance Routing Hierarchy

- Segmented, Hierarchical Routing and Clock Structure

Advanced I/Os

- 1.2 V, 1.5 V, 1.8 V, 2.5 V, and 3.3 V Mixed-Voltage Operation
- Bank-Selectable I/O Voltages—up to 4 Banks per Chip
- Single-Ended I/O Standards: LVTTTL, LVCMOS 3.3 V / 2.5 V / 1.8 V / 1.5 V / 1.2 V
- Wide Range Power Supply Voltage Support per JESD8-B, Allowing I/Os to Operate from 2.7 V to 3.6 V
- Wide Range Power Supply Voltage Support per JESD8-12, Allowing I/Os to Operate from 1.14 V to 1.575 V
- I/O Registers on Input, Output, and Enable Paths
- Selectable Schmitt Trigger Inputs
- Hot-Swappable and Cold-Sparing I/Os
- Programmable Output Slew Rate and Drive Strength
- Weak Pull-Up/-Down
- IEEE 1149.1 (JTAG) Boundary Scan Test
- Pin-Compatible Packages across the IGLOO Family

Clock Conditioning Circuit (CCC) and PLL[†]

- Up to Six CCC Blocks, One with an Integrated PLL
- Configurable Phase Shift, Multiply/Divide, Delay Capabilities, and External Feedback
- Wide Input Frequency Range (1.5 MHz up to 250 MHz)

Embedded Memory

- 1 kbit of FlashROM User Nonvolatile Memory
- SRAMs and FIFOs with Variable-Aspect-Ratio 4,608-Bit RAM Blocks (x1, x2, x4, x9, and x18 organizations)[†]
- True Dual-Port SRAM (except x 18 organization)[†]

Enhanced Commercial Temperature Range

- -20°C to +70°C

Table 1 • IGLOO nano Devices

IGLOO nano Devices	AGLN010	AGLN015	AGLN020	AGLN030 ¹	AGLN060	AGLN125	AGLN250
System Gates	10 k	15 k	20 k	30 k	60 k	125 k	250 k
Typical Equivalent Macrocells	86	128	172	256	512	1,024	2,048

I/O Banks	2	3	3	2	2	2	4
Maximum User I/Os (packaged device)	34	49	52	77	71	71	68
Maximum User I/Os (Known Good Die)	34	–	52	83	71	71	68
Package Pins							
UC/CS	UC36		UC81, CS81	UC81, CS81	CS81	CS81	CS81
QFN	QN48	QN68	QN68	QN48, QN68			
VQFP				VQ100	VQ100	VQ100	VQ100

Notes:

1. AGLN030 is available in the Z feature grade only and offers package compatibility with the lower density nano devices. Refer to "IGLOO nano Ordering Information" on page III.
2. AGLN030 and smaller devices do not support this feature.
3. AGLN060, AGLN125, and AGLN250 in the CS81 package do not support PLLs.
4. For higher densities and support of additional features, refer to the IGLOO and IGLOOe handbooks.

[†] AGLN030 and smaller devices do not support this feature.

I/Os Per Package

IGLOO nano Devices	AGLN010	AGLN015	AGLN020	AGLN030 ¹	AGLN060	AGLN125	AGLN250
Known Good Die	34	–	52	83	71	71	68
UC36	23						
QN48	34			34			
QN68		49	49	49			
UC81			52	66			
CS81			52	66	60	60	60
VQ100				77	71	71	68

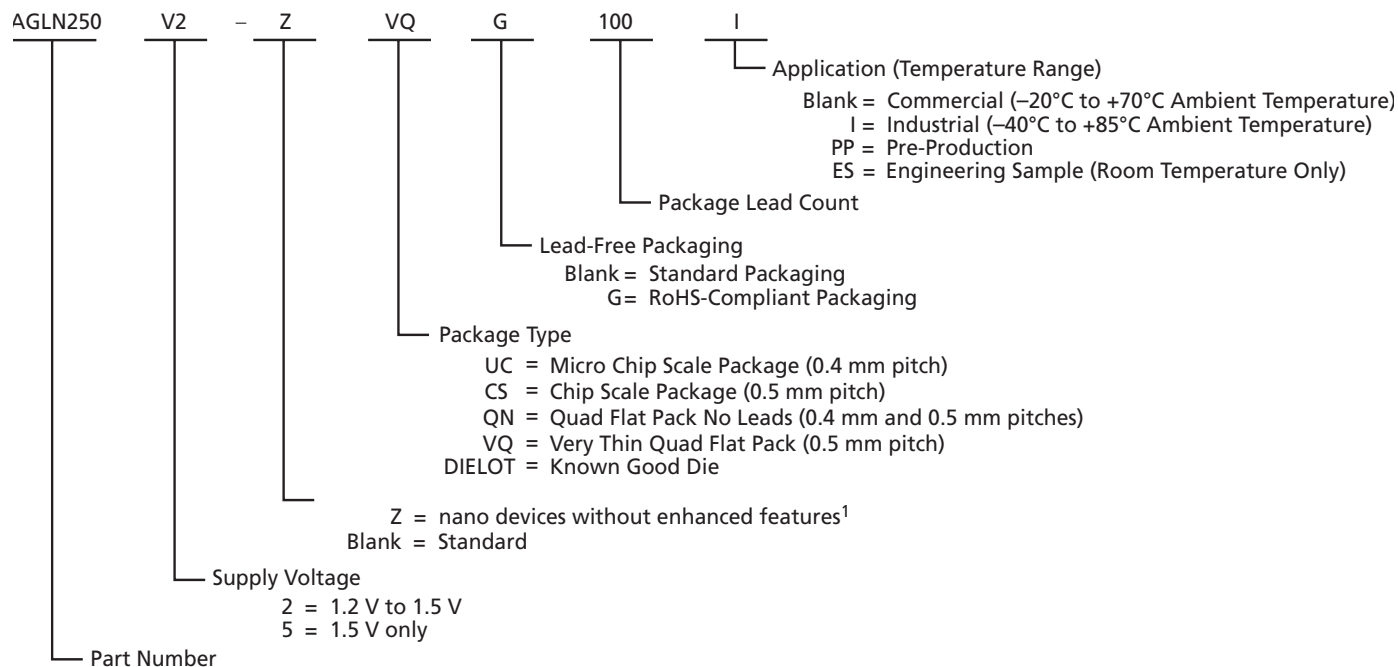

Notes:

1. AGLN030 is available in the Z feature grade only and offers package compatibility with the lower density nano devices. Refer to "IGLOO nano Ordering Information" on page III.
2. When considering migrating your design to a lower- or higher-density device, refer to the IGLOO Handbook to ensure compliance with design and board migration requirements.
3. When the Flash*Freeze pin is used to directly enable Flash*Freeze mode and not used as a regular I/O, the number of single-ended user I/Os available is reduced by one.
4. "G" indicates RoHS-compliant packages. Refer to "IGLOO nano Ordering Information" on page III for the location of the "G" in the part number. For nano devices, the VQ100 package is offered in both leaded and RoHS-compliant versions. All other packages are RoHS-compliant only.

Table 2 • IGLOO FPGAs Package Sizes Dimensions

Packages	UC36	UC81	CS81	QN48	QN68	VQ100
Length × Width (mm \ mm)	3 x 3	4 x 4	5 x 5	6 x 6	8 x 8	14 x 14
Nominal Area (mm ²)	9	16	36	36	64	196
Pitch (mm)	0.4	0.4	0.5	0.4	0.4	0.5
Height (mm)	0.80	0.80	0.80	0.90	0.90	1.20

IGLOO nano Ordering Information

IGLOO nano Devices

AGLN010 = 10,000 System Gates
 AGLN015 = 15,000 System Gates
 AGLN020 = 20,000 System Gates
 AGLN030 = 30,000 System Gates
 AGLN060 = 60,000 System Gates
 AGLN125 = 125,000 System Gates
 AGLN250 = 250,000 System Gates

Notes:

- For the AGLN060, AGLN125, and AGLN250, the Z feature grade does not support the enhanced nano features of Schmitt trigger input, bus hold, cold-sparing, and hot-swap I/O capability. The AGLN030 Z feature grade does not support Schmitt trigger input and bus hold. For the VQ100, CS81, UC81, QN68, and QN48 packages, the Z feature grade and the N part number are not marked on the device.
- Marking Information: IGLOO nano V2 devices do not have V2 marking, but IGLOO nano V5 devices are marked with a V5 designator.

Device Marking

Actel normally topside marks the full ordering part number on each device. There are some exceptions to this, such as some of the Z feature grade nano devices, the V2 designator for IGLOO devices, and packages where space is physically limited. Packages that have limited characters available are UC36, UC81, CS81, QN48, QN68, and QFN132. On these specific packages, a subset of the device marking will be used that includes the required legal information and as much of the part number as allowed by character limitation of the device. In this case, devices will have a truncated device marking and may exclude the applications markings, such as the I designator for Industrial Devices or the ES designator for Engineering Samples.

Figure 1 shows an example of device marking based on the AGL030V5-UCG81. The actual mark will vary by the device/package combination ordered.

Figure 1 • Example of Device Marking for Small Form Factor Packages

IGLOO nano Product Available in the Z Feature Grade

Devices	AGLN030	AGLN060	AGLN125	AGLN250
Packages	QN48	–	–	–
	QN68	–	–	–
	UC81	–	–	–
	CS81	CS81	CS81	CS81
	VQ100	VQ100	VQ100	VQ100

Temperature Grade Offerings

Package	AGLN010	AGLN015	AGLN020	AGLN030	AGLN060	AGLN125	AGLN250
UC36	C, I	–	–	–	–	–	–
QN48	C, I	–	–	C, I	–	–	–
QN68	–	C, I	C, I	C, I	–	–	–
UC81	–	–	C, I	C, I	–	–	–
CS81	–	–	C, I	C, I	C, I	C, I	C, I
VQ100	–	–	–	C, I	C, I	C, I	C, I

Notes:

1. C = Commercial temperature range: –20°C to 70°C ambient temperature.
2. I = Industrial temperature range: –40°C to 85°C ambient temperature.

Contact your local Actel representative for device availability: <http://www.actel.com/contact/default.aspx>.

1 – IGLOO nano Device Overview

General Description

The IGLOO family of flash FPGAs, based on a 130-nm flash process, offers the lowest power FPGA, a single-chip solution, small footprint packages, reprogrammability, and an abundance of advanced features.

The Flash*Freeze technology used in IGLOO nano devices enables entering and exiting an ultra-low-power mode that consumes nanoPower while retaining SRAM and register data. Flash*Freeze technology simplifies power management through I/O and clock management with rapid recovery to operation mode.

The Low Power Active capability (static idle) allows for ultra-low-power consumption while the IGLOO nano device is completely functional in the system. This allows the IGLOO nano device to control system power management based on external inputs (e.g., scanning for keyboard stimulus) while consuming minimal power.

Nonvolatile flash technology gives IGLOO nano devices the advantage of being a secure, low-power, single-chip solution that is live at power-up (LAPU). The IGLOO nano device is reprogrammable and offers time-to-market benefits at an ASIC-level unit cost.

These features enable designers to create high-density systems using existing ASIC or FPGA design flows and tools.

IGLOO nano devices offer 1 kbit of on-chip, reprogrammable, nonvolatile FlashROM storage as well as clock conditioning circuitry based on an integrated phase-locked loop (PLL). The AGLN030 and smaller devices have no PLL or RAM support. IGLOO nano devices have up to 250 k system gates, supported with up to 36 kbits of true dual-port SRAM and up to 71 user I/Os.

IGLOO nano devices increase the breadth of the IGLOO product line by adding new features and packages for greater customer value in high volume consumer, portable, and battery-backed markets. Features such as smaller footprint packages designed with two-layer PCBs in mind, power consumption measured in nanoPower, Schmitt trigger, and bus hold functionality make these devices ideal for deployment in applications that require high levels of flexibility and low cost.

Flash*Freeze Technology

The IGLOO nano device offers unique Flash*Freeze technology, allowing the device to enter and exit ultra-low-power Flash*Freeze mode. IGLOO nano devices do not need additional components to turn off I/Os or clocks while retaining the design information, SRAM content, and registers. Flash*Freeze technology is combined with in-system programmability, which enables users to quickly and easily upgrade and update their designs in the final stages of manufacturing or in the field. The ability of IGLOO nano V2 devices to support a wide range of core voltage (1.2 V to 1.5 V) allows further reduction in power consumption, thus achieving the lowest total system power.

During Flash*Freeze mode, each I/O can be set to the following configurations: hold previous state, tristate, HIGH, or LOW.

The availability of low-power modes, combined with reprogrammability, a single-chip and single-voltage solution, and small-footprint packages make IGLOO nano devices the best fit for portable electronics.

Flash Advantages

Low Power

Flash-based IGLOO nano devices exhibit power characteristics similar to those of an ASIC, making them an ideal choice for power-sensitive applications. IGLOO nano devices have only a very limited power-on current surge and no high-current transition period, both of which occur on many FPGAs.

IGLOO nano devices also have low dynamic power consumption to further maximize power savings; power is reduced even further by the use of a 1.2 V core voltage.

Low dynamic power consumption, combined with low static power consumption and Flash*Freeze technology, gives the IGLOO nano device the lowest total system power offered by any FPGA.

Security

Nonvolatile, flash-based IGLOO nano devices do not require a boot PROM, so there is no vulnerable external bitstream that can be easily copied. IGLOO nano devices incorporate FlashLock, which provides a unique combination of reprogrammability and design security without external overhead, advantages that only an FPGA with nonvolatile flash programming can offer.

IGLOO nano devices utilize a 128-bit flash-based lock and a separate AES key to secure programmed intellectual property and configuration data. In addition, all FlashROM data in IGLOO nano devices can be encrypted prior to loading, using the industry-leading AES-128 (FIPS192) bit block cipher encryption standard. AES was adopted by the National Institute of Standards and Technology (NIST) in 2000 and replaces the 1977 DES standard. IGLOO nano devices have a built-in AES decryption engine and a flash-based AES key that make them the most comprehensive programmable logic device security solution available today. IGLOO nano devices with AES-based security allow for secure, remote field updates over public networks such as the Internet, and ensure that valuable IP remains out of the hands of system overbuilders, system cloners, and IP thieves. The contents of a programmed IGLOO nano device cannot be read back, although secure design verification is possible.

Security, built into the FPGA fabric, is an inherent component of IGLOO nano devices. The flash cells are located beneath seven metal layers, and many device design and layout techniques have been used to make invasive attacks extremely difficult. IGLOO nano devices, with FlashLock and AES security, are unique in being highly resistant to both invasive and noninvasive attacks. Your valuable IP is protected and secure, making remote ISP possible. An IGLOO nano device provides the most impenetrable security for programmable logic designs.

Single Chip

Flash-based FPGAs store their configuration information in on-chip flash cells. Once programmed, the configuration data is an inherent part of the FPGA structure, and no external configuration data needs to be loaded at system power-up (unlike SRAM-based FPGAs). Therefore, flash-based IGLOO nano FPGAs do not require system configuration components such as EEPROMs or microcontrollers to load device configuration data. This reduces bill-of-materials costs and PCB area, and increases security and system reliability.

Live at Power-Up

Actel flash-based IGLOO nano devices support Level 0 of the LAPU classification standard. This feature helps in system component initialization, execution of critical tasks before the processor wakes up, setup and configuration of memory blocks, clock generation, and bus activity management. The LAPU feature of flash-based IGLOO nano devices greatly simplifies total system design and reduces total system cost, often eliminating the need for CPLDs and clock generation PLLs. In addition, glitches and brownouts in system power will not corrupt the IGLOO nano device's flash configuration, and unlike SRAM-based FPGAs, the device will not have to be reloaded when system power is restored. This enables the reduction or complete removal of the configuration PROM, expensive voltage monitor, brownout detection, and clock generator devices from the PCB design. Flash-based IGLOO nano devices simplify total system design and reduce cost and design risk while increasing system reliability and improving system initialization time.

IGLOO nano flash FPGAs enable the user to quickly enter and exit Flash*Freeze mode. This is done almost instantly (within 1 μ s) and the device retains configuration and data in registers and RAM.

Unlike SRAM-based FPGAs, the device does not need to reload configuration and design state from external memory components; instead it retains all necessary information to resume operation immediately.

Reduced Cost of Ownership

Advantages to the designer extend beyond low unit cost, performance, and ease of use. Unlike SRAM-based FPGAs, flash-based IGLOO nano devices allow all functionality to be live at power-up; no external boot PROM is required. On-board security mechanisms prevent access to all the programming information and enable secure remote updates of the FPGA logic. Designers can perform secure remote in-system reprogramming to support future design iterations and field upgrades with confidence that valuable intellectual property cannot be compromised or copied. Secure ISP can be performed using the industry-standard AES algorithm. The IGLOO nano device architecture mitigates the need for ASIC migration at higher user volumes. This makes IGLOO nano devices cost-effective ASIC replacement solutions, especially for applications in the consumer, networking/communications, computing, and avionics markets.

With a variety of devices under \$1, Actel IGLOO nano FPGAs enable cost-effective implementation of programmable logic and quick time to market.

Firm-Error Immunity

Firm errors occur most commonly when high-energy neutrons, generated in the upper atmosphere, strike a configuration cell of an SRAM FPGA. The energy of the collision can change the state of the configuration cell and thus change the logic, routing, or I/O behavior in an unpredictable way. These errors are impossible to prevent in SRAM FPGAs. The consequence of this type of error can be a complete system failure. Firm errors do not exist in the configuration memory of IGLOO nano flash-based FPGAs. Once it is programmed, the flash cell configuration element of IGLOO nano FPGAs cannot be altered by high-energy neutrons and is therefore immune to them. Recoverable (or soft) errors occur in the user data SRAM of all FPGA devices. These can easily be mitigated by using error detection and correction (EDAC) circuitry built into the FPGA fabric.

Advanced Flash Technology

The IGLOO nano device offers many benefits, including nonvolatility and reprogrammability, through an advanced flash-based, 130-nm LVCMOS process with seven layers of metal. Standard CMOS design techniques are used to implement logic and control functions. The combination of fine granularity, enhanced flexible routing resources, and abundant flash switches allows for very high logic utilization without compromising device routability or performance. Logic functions within the device are interconnected through a four-level routing hierarchy.

IGLOO nano FPGAs utilize design and process techniques to minimize power consumption in all modes of operation.

Advanced Architecture

The proprietary IGLOO nano architecture provides granularity comparable to standard-cell ASICs. The IGLOO nano device consists of five distinct and programmable architectural features (Figure 1-3 on page 1-5 to Figure 1-4 on page 1-5):

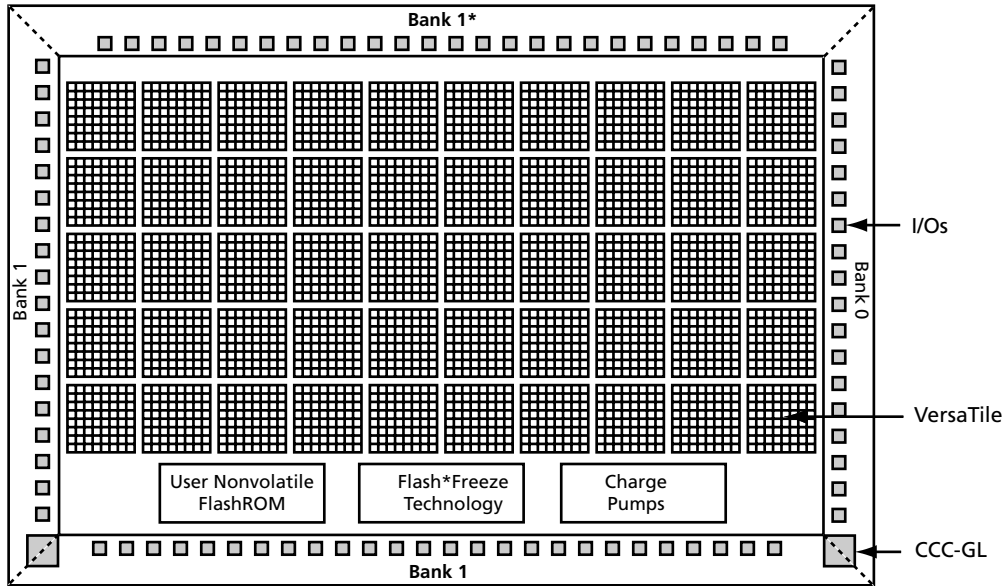

- Flash*Freeze technology
- FPGA VersaTiles
- Dedicated FlashROM
- Dedicated SRAM/FIFO memory[†]
- Extensive CCCs and PLLs[†]
- Advanced I/O structure

The FPGA core consists of a sea of VersaTiles. Each VersaTile can be configured as a three-input logic function, a D-flip-flop (with or without enable), or a latch by programming the appropriate flash switch interconnections. The versatility of the IGLOO nano core tile as either a three-input lookup table (LUT) equivalent or a D-flip-flop/latch with enable allows for efficient use of the FPGA fabric. The VersaTile capability is unique to the Actel ProASIC® family of third-generation-

[†] The AGLN030 and smaller devices do not support PLL or SRAM.

architecture flash FPGAs. VersaTiles are connected with any of the four levels of routing hierarchy. Flash switches are distributed throughout the device to provide nonvolatile, reconfigurable interconnect programming. Maximum core utilization is possible for virtually any design.

In addition, extensive on-chip programming circuitry enables rapid, single-voltage (3.3 V) programming of IGLOO nano devices via an IEEE 1532 JTAG interface.

Figure 1-4 • IGLOO Device Architecture Overview with Four I/O Banks (AGLN250)

Flash*Freeze Technology

The IGLOO nano device has an ultra-low-power static mode, called Flash*Freeze mode, which retains all SRAM and register information and can still quickly return to normal operation. Flash*Freeze technology enables the user to quickly (within 1 μ s) enter and exit Flash*Freeze mode by activating the Flash*Freeze pin while all power supplies are kept at their original values. I/Os, global I/Os, and clocks can still be driven and can be toggling without impact on power consumption, and the device retains all core registers, SRAM information, and I/O states. I/Os can be individually configured to either hold their previous state or be tristated during Flash*Freeze mode.

Alternatively, I/Os can be set to a specific state using weak pull-up or pull-down I/O attribute configuration. No power is consumed by the I/O banks, clocks, JTAG pins, or PLL, and the device consumes as little as 2 μ W in this mode.

Flash*Freeze technology allows the user to switch to Active mode on demand, thus simplifying the power management of the device.

The Flash*Freeze pin (active low) can be routed internally to the core to allow the user's logic to decide when it is safe to transition to this mode. Refer to Figure 1-5 for an illustration of entering/exiting Flash*Freeze mode. It is also possible to use the Flash*Freeze pin as a regular I/O if Flash*Freeze mode usage is not planned.

Figure 1-5 • IGLOO nano Flash*Freeze Mode

VersaTiles

The IGLOO nano core consists of VersaTiles, which have been enhanced beyond the ProASIC^{PLUS}® core tiles. The IGLOO nano VersaTile supports the following:

- All 3-input logic functions—LUT-3 equivalent
- Latch with clear or set
- D-flip-flop with clear or set
- Enable D-flip-flop with clear or set

Refer to Figure 1-6 for VersaTile configurations.

Figure 1-6 • VersaTile Configurations

User Nonvolatile FlashROM

Actel IGLOO nano devices have 1 kbit of on-chip, user-accessible, nonvolatile FlashROM. The FlashROM can be used in diverse system applications:

- Internet protocol addressing (wireless or fixed)
- System calibration settings
- Device serialization and/or inventory control
- Subscription-based business models (for example, set-top boxes)
- Secure key storage for secure communications algorithms
- Asset management/tracking
- Date stamping
- Version management

The FlashROM is written using the standard IGLOO nano IEEE 1532 JTAG programming interface. The core can be individually programmed (erased and written), and on-chip AES decryption can be used selectively to securely load data over public networks (except in the AGLN030 and smaller devices), as in security keys stored in the FlashROM for a user design.

The FlashROM can be programmed via the JTAG programming interface, and its contents can be read back either through the JTAG programming interface or via direct FPGA core addressing. Note that the FlashROM can only be programmed from the JTAG interface and cannot be programmed from the internal logic array.

The FlashROM is programmed as 8 banks of 128 bits; however, reading is performed on a byte-by-byte basis using a synchronous interface. A 7-bit address from the FPGA core defines which of the 8 banks and which of the 16 bytes within that bank are being read. The three most significant bits (MSBs) of the FlashROM address determine the bank, and the four least significant bits (LSBs) of the FlashROM address define the byte.

The Actel IGLOO nano development software solutions, Libero® Integrated Design Environment (IDE) and Designer, have extensive support for the FlashROM. One such feature is auto-generation of sequential programming files for applications requiring a unique serial number in each part. Another feature enables the inclusion of static data for system version control. Data for the FlashROM can be generated quickly and easily using Actel Libero IDE and Designer software tools. Comprehensive programming file support is also included to allow for easy programming of large numbers of parts with differing FlashROM contents.

SRAM and FIFO

IGLOO nano devices (except the AGLN030 and smaller devices) have embedded SRAM blocks along their north and south sides. Each variable-aspect-ratio SRAM block is 4,608 bits in size. Available memory configurations are 256×18, 512×9, 1k×4, 2k×2, and 4k×1 bits. The individual blocks have independent read and write ports that can be configured with different bit widths on each port. For example, data can be sent through a 4-bit port and read as a single bitstream. The embedded SRAM blocks can be initialized via the device JTAG port (ROM emulation mode) using the UJTAG macro (except in the AGLN030 and smaller devices).

In addition, every SRAM block has an embedded FIFO control unit. The control unit allows the SRAM block to be configured as a synchronous FIFO without using additional core VersaTiles. The FIFO width and depth are programmable. The FIFO also features programmable Almost Empty (AEMPTY) and Almost Full (AFULL) flags in addition to the normal Empty and Full flags. The embedded FIFO control unit contains the counters necessary for generation of the read and write address pointers. The embedded SRAM/FIFO blocks can be cascaded to create larger configurations.

PLL and CCC

Higher density IGLOO nano devices using either the two I/O bank or four I/O bank architectures provide designers with very flexible clock conditioning capabilities. AGLN060, AGLN125, and AGLN250 contain six CCCs. One CCC (center west side) has a PLL. The AGLN030 and smaller devices use different CCCs in their architecture (CCC-GL). These CCC-GLs contain a global MUX but do not have any PLLs or programmable delays.

For devices using the six CCC block architecture, these are located at the four corners and the centers of the east and west sides. All six CCC blocks are usable; the four corner CCCs and the east CCC allow simple clock delay operations as well as clock spine access.

The inputs of the six CCC blocks are accessible from the FPGA core or from dedicated connections to the CCC block, which are located near the CCC.

The CCC block has these key features:

- Wide input frequency range (f_{IN_CCC}) = 1.5 MHz up to 250 MHz
- Output frequency range (f_{OUT_CCC}) = 0.75 MHz up to 250 MHz
- 2 programmable delay types for clock skew minimization
- Clock frequency synthesis (for PLL only)

Additional CCC specifications:

- Internal phase shift = 0°, 90°, 180°, and 270°. Output phase shift depends on the output divider configuration (for PLL only).
- Output duty cycle = 50% ± 1.5% or better (for PLL only)
- Low output jitter: worst case < 2.5% × clock period peak-to-peak period jitter when single global network used (for PLL only)
- Maximum acquisition time is 300 μs (for PLL only)
- Exceptional tolerance to input period jitter—allowable input jitter is up to 1.5 ns (for PLL only)
- Four precise phases; maximum misalignment between adjacent phases of 40 ps × 250 MHz / f_{OUT_CCC} (for PLL only)

Global Clocking

IGLOO nano devices have extensive support for multiple clocking domains. In addition to the CCC and PLL support described above, there is a comprehensive global clock distribution network.

Each VersaTile input and output port has access to nine VersaNets: six chip (main) and three quadrant global networks. The VersaNets can be driven by the CCC or directly accessed from the core via multiplexers (MUXes). The VersaNets can be used to distribute low-skew clock signals or for rapid distribution of high-fanout nets.

I/Os with Advanced I/O Standards

IGLOO nano FPGAs feature a flexible I/O structure, supporting a range of voltages (1.2 V, 1.5 V, 1.8 V, 2.5 V, 3.0 V wide range, and 3.3 V).

The I/Os are organized into banks with two, three, or four banks per device. The configuration of these banks determines the I/O standards supported.

Each I/O module contains several input, output, and enable registers. These registers allow the implementation of various single-data-rate applications for all versions of nano devices and double-data-rate applications for the AGLN060, AGLN125, and AGLN250 devices.

IGLOO nano devices support LVTTL and LVCMOS I/O standards, are hot-swappable, and support cold-sparing and Schmitt trigger.

Wide Range I/O Support

Actel nano devices support JEDEC-defined wide range I/O operation. IGLOO nano devices support both the JESD8-B specification, covering both 3 V and 3.3 V supplies, for an effective operating range of 2.7 V to 3.6 V, and JESD8-12 with its 1.2 V nominal, supporting an effective operating range of 1.14 V to 1.575 V.

Wider I/O range means designers can eliminate power supplies or power conditioning components from the board or move to less costly components with greater tolerances. Wide range eases I/O bank management and provides enhanced protection from system voltage spikes, while providing the flexibility to easily run custom voltage applications.

Part Number and Revision Date

Part Number 51700110-001-6
Revised April 2009

List of Changes

The following table lists critical changes that were made in the current version of the document.

Previous Version	Changes in Current Version (Advance v0.7)	Page
Advance v0.6 (February 2009)	The –F speed grade is no longer offered for IGLOO PLUS devices. The speed grade column and note regarding –F speed grade were removed from "IGLOO nano Ordering Information". The "Speed Grade and Temperature Grade Matrix" section was removed.	III, IV
Advance v0.5 (February 2009)	The QN100 package was removed for all devices.	N/A
	Table 1 · IGLOO nano Devices was updated to change the maximum user I/Os for AGLN030 from 81 to 77.	I
	The "Device Marking" section is new.	III
Advance v0.4 (December 2008)	The following table note was removed from Table 1 · IGLOO nano Devices: "Six chip (main) and three quadrant global networks are available for AGLN060 and above."	I
	The CS81 package was added for AGLN250 in the "IGLOO nano Product Available in the Z Feature Grade" table.	IV
Advance v0.3 (November 2008)	The second table note in Table 1 · IGLOO nano Devices was revised to state, "AGLN060, AGLN125, and AGLN250 in the CS81 package do not support PLLs. AGLN030 and smaller devices do not support this feature."	I
	The I/Os per package for CS81 were revised to 60 for AGLN060, AGLN125, and AGLN250 in the "I/Os Per Package" table.	II
Advance v0.2 (October 2008)	The "Advanced I/Os" section was updated to include wide power supply voltage support for 1.14 V to 1.575 V.	I
	The AGLN030 device was added to product tables and replaces AGL030 entries that were formerly in the tables.	I to IV
	The "I/Os Per Package" table was updated for the CS81 package to change the number of I/Os for AGLN060, AGLN125, and AGLN250 from 66 to 64.	II
	The "Wide Range I/O Support" section is new.	1-8
Advance v0.1 (October 2008)	The following tables and sections were updated to add the UC81 and CS81 packages for AGL030: "IGLOO nano Devices" "I/Os Per Package" "IGLOO nano Product Available in the Z Feature Grade" "Temperature Grade Offerings"	N/A
	The "I/Os Per Package" table was updated to add the following information to table note 4: "For nano devices, the VQ100 package is offered in both leaded and RoHS-compliant versions. All other packages are RoHS-compliant only."	II
	The "IGLOO nano Product Available in the Z Feature Grade" section was updated to remove QN100 for AGLN250.	IV
	The device architecture figures, Figure 1-3 · IGLOO Device Architecture Overview with Two I/O Banks (AGLN060, AGLN125) through Figure 1-4 · IGLOO Device Architecture Overview with Four I/O Banks (AGLN250), were revised. Figure 1-1 · IGLOO Device Architecture Overview with Two I/O Banks and No RAM (AGLN010 and AGLN030) is new.	1-4 through 1-5

Previous Version	Changes in Current Version (Advance v0.7)	Page
Advance v0.1 (continued)	The "PLL and CCC" section was revised to include information about CCC-GLs in AGLN020 and smaller devices.	1-7
	The "I/Os with Advanced I/O Standards" section was revised to add information about IGLOO nano devices supporting double-data-rate applications.	1-8

2 – IGLOO nano DC and Switching Characteristics

General Specifications

The Z feature grade does not support the enhanced nano features of Schmitt trigger input, Flash*Freeze bus hold, cold-sparing, and hot-swap I/O capability. Refer to the ordering information in the *IGLOO nano Product Brief* for more information.

Operating Conditions

Stresses beyond those listed in [Table 2-1](#) may cause permanent damage to the device.

Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Absolute Maximum Ratings are stress ratings only; functional operation of the device at these or any other conditions beyond those listed under the Recommended Operating Conditions specified in [Table 2-2 on page 2-2](#) is not implied.

Table 2-1 • Absolute Maximum Ratings

Symbol	Parameter	Limits	Units
V _{CC}	DC core supply voltage	–0.3 to 1.65	V
V _{JTAG}	JTAG DC voltage	–0.3 to 3.75	V
V _{PUMP}	Programming voltage	–0.3 to 3.75	V
V _{CCPLL}	Analog power supply (PLL)	–0.3 to 1.65	V
V _{CCI}	DC I/O buffer supply voltage	–0.3 to 3.75	V
V _I	I/O input voltage	–0.3 V to 3.6 V	V
T _{STG} ²	Storage temperature	–65 to +150	°C
T _J ²	Junction temperature	+125	°C

Notes:

1. The device should be operated within the limits specified by the datasheet. During transitions, the input signal may undershoot or overshoot according to the limits shown in [Table 2-4 on page 2-3](#).
2. For flash programming and retention maximum limits, refer to [Table 2-3 on page 2-2](#), and for recommended operating limits, refer to [Table 2-2 on page 2-2](#).

Table 2-2 • Recommended Operating Conditions ¹

Symbol	Parameter		Extended Commercial	Industrial	Units
T _A	Ambient temperature		-20 to +70 ²	-40 to +85 ²	°C
T _J	Junction temperature		-20 to +85 ²	-40 to +100 ²	°C
V _{CC}	1.5 V DC core supply voltage ³		1.425 to 1.575	1.425 to 1.575	V
	1.2 V–1.5 V wide range core voltage ⁴		1.14 to 1.575	1.14 to 1.575	V
V _{JTAG}	JTAG DC voltage		1.425 to 3.6	1.425 to 3.6	V
V _{PUMP} ⁵	Programming voltage	Programming mode	3.15 to 3.45	3.15 to 3.45	V
		Operation	0 to 3.45	0 to 3.45	V
V _{CCPLL} ⁶	Analog power supply (PLL)	1.5 V DC core supply voltage ³	1.425 to 1.575	1.425 to 1.575	V
		1.2 V–1.5 V wide range core supply voltage ⁴	1.14 to 1.575	1.14 to 1.575	V
V _{CCI} and VMV ^{7,9}	1.2 V DC supply voltage ⁴		1.14 to 1.26	1.14 to 1.26	V
	1.2 V DC wide range supply voltage ⁴		1.14 to 1.575	1.14 to 1.575	V
	1.5 V DC supply voltage		1.425 to 1.575	1.425 to 1.575	
	1.8 V DC supply voltage		1.7 to 1.9	1.7 to 1.9	V
	2.5 V DC supply voltage		2.3 to 2.7	2.3 to 2.7	V
	3.3 V DC supply voltage		3.0 to 3.6	3.0 to 3.6	V
	3.3 V DC wide range supply voltage ⁸		2.7 to 3.6	2.7 to 3.6	

Notes:

1. All parameters representing voltages are measured with respect to GND unless otherwise specified.
2. To ensure targeted reliability standards are met across ambient and junction operating temperatures, Actel recommends that the user follow best design practices using Actel's timing and power simulation tools.
3. For IGLOO[®] nano V5 devices
4. For IGLOO nano V2 devices only, operating at $V_{CCI} \geq V_{CC}$
5. V_{PUMP} can be left floating during operation (not programming mode).
6. V_{CCPLL} pins should be tied to V_{CC} pins. See [Pin Descriptions](#) for further information.
7. VMV pins must be connected to the corresponding V_{CCI} pins. See [Pin Descriptions](#) for further information.
8. 3.3 V wide range is compliant to the JESD8-B specification and supports 3.0 V V_{CCI} operation.
9. The ranges given here are for power supplies only. The recommended input voltage ranges specific to each I/O standard are given in [Table 2-20 on page 2-19](#). V_{CCI} should be at the same voltage within a given I/O bank.

Table 2-3 • Flash Programming Limits – Retention, Storage, and Operating Temperature ¹

Product Grade	Programming Cycles	Program Retention (biased/unbiased)	Maximum Storage Temperature T _{STG} (°C) ²	Maximum Operating Junction Temperature T _J (°C) ²
Commercial	500	20 years	110	100
Industrial	500	20 years	110	100

Notes:

1. This is a stress rating only; functional operation at any condition other than those indicated is not implied.
2. These limits apply for program/data retention only. Refer to [Table 2-1 on page 2-1](#) and [Table 2-2](#) for device operating conditions and absolute limits.

Table 2-4 • Overshoot and Undershoot Limits ¹

V _{CCI}	Average V _{CCI} -GND Overshoot or Undershoot Duration as a Percentage of Clock Cycle ²	Maximum Overshoot/Undershoot ²
2.7 V or less	10%	1.4 V
	5%	1.49 V
3 V	10%	1.1 V
	5%	1.19 V
3.3 V	10%	0.79 V
	5%	0.88 V
3.6 V	10%	0.45 V
	5%	0.54 V

Notes:

1. Based on reliability requirements at 85°C.
2. The duration is allowed at one out of six clock cycles. If the overshoot/undershoot occurs at one out of two cycles, the maximum overshoot/undershoot has to be reduced by 0.15 V.

I/O Power-Up and Supply Voltage Thresholds for Power-On Reset (Commercial and Industrial)

Sophisticated power-up management circuitry is designed into every IGLOO nano device. These circuits ensure easy transition from the powered-off state to the powered-up state of the device. The many different supplies can power up in any sequence with minimized current spikes or surges. In addition, the I/O will be in a known state through the power-up sequence. The basic principle is shown in Figure 2-1 on page 2-4.

There are five regions to consider during power-up.

IGLOO nano I/Os are activated only if ALL of the following three conditions are met:

1. V_{CC} and V_{CCI} are above the minimum specified trip points (Figure 2-1 and Figure 2-2 on page 2-5).
2. V_{CCI} > V_{CC} - 0.75 V (typical)
3. Chip is in the operating mode.

V_{CCI} Trip Point:

Ramping up (V5 devices): 0.6 V < trip_point_up < 1.2 V

Ramping down (V5 devices): 0.5 V < trip_point_down < 1.1 V

Ramping up (V2 devices): 0.75 V < trip_point_up < 1.05 V

Ramping down (V2 devices): 0.65 V < trip_point_down < 0.95 V

V_{CC} Trip Point:

Ramping up (V5 devices): 0.6 V < trip_point_up < 1.1 V

Ramping down (V5 devices): 0.5 V < trip_point_down < 1.0 V

Ramping up (V2 devices): 0.65 V < trip_point_up < 1.05 V

Ramping down (V2 devices): 0.55 V < trip_point_down < 0.95 V

V_{CC} and V_{CCI} ramp-up trip points are about 100 mV higher than ramp-down trip points. This specifically built-in hysteresis prevents undesirable power-up oscillations and current surges. Note the following:

- During programming, I/Os become tristated and weakly pulled up to V_{CCI}.
- JTAG supply, PLL power supplies, and charge pump V_{PUMP} supply have no influence on I/O behavior.

PLL Behavior at Brownout Condition

Actel recommends using monotonic power supplies or voltage regulators to ensure proper power-up behavior. Power ramp-up should be monotonic at least until V_{CC} and V_{CCPLX} exceed brownout activation levels (see Figure 2-1 and Figure 2-2 on page 2-5 for more details).

When PLL power supply voltage and/or V_{CC} levels drop below the V_{CC} brownout levels ($0.75\text{ V} \pm 0.25\text{ V}$ for V5 devices, and $0.75\text{ V} \pm 0.2\text{ V}$ for V2 devices), the PLL output lock signal goes LOW and/or the output clock is lost. Refer to the "Brownout Voltage" section in the *Power-Up/Down Behavior of Low-Power Flash Devices* chapter of the *ProASIC3* and *ProASIC3E* handbooks for information on clock and lock recovery.

Internal Power-Up Activation Sequence

1. Core
2. Input buffers
3. Output buffers, after 200 ns delay from input buffer activation

To make sure the transition from input buffers to output buffers is clean, ensure that there is no path longer than 100 ns from input buffer to output buffer in your design.

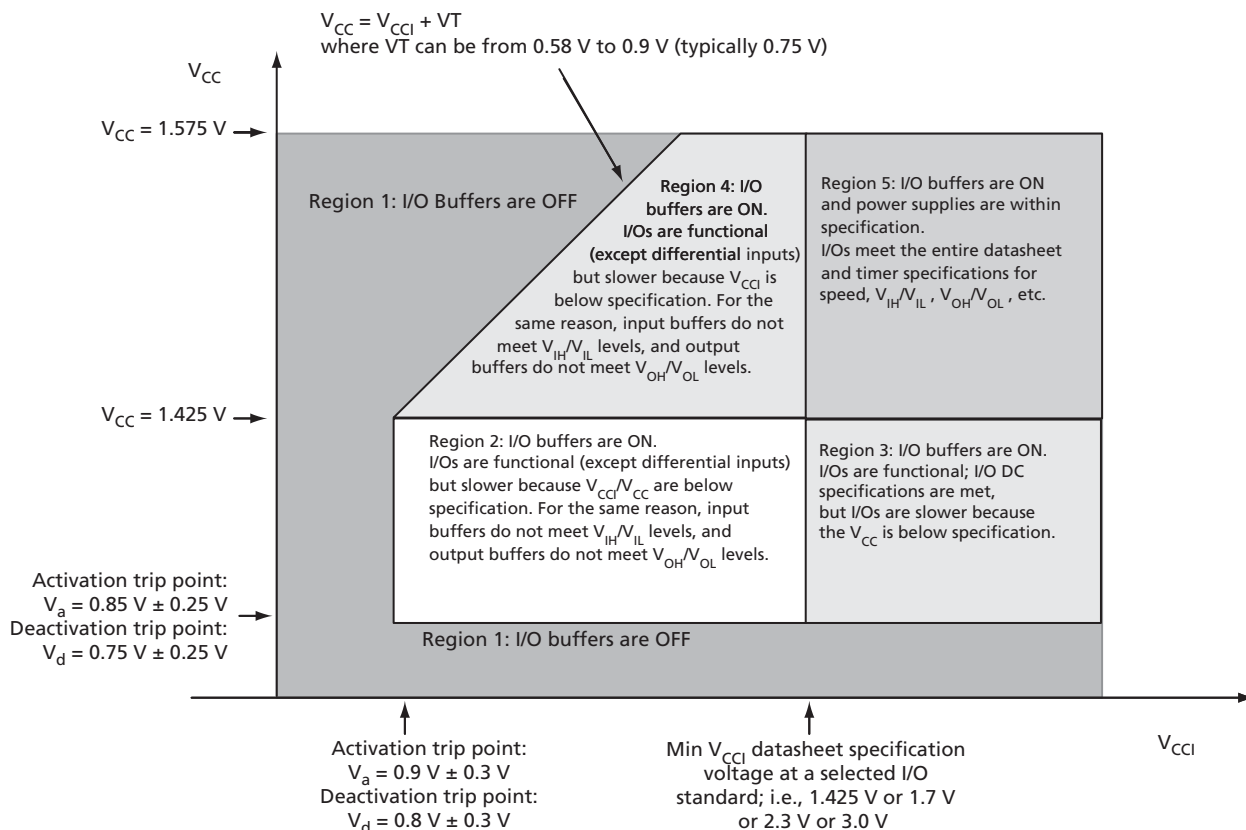

Figure 2-1 • V5 Devices – I/O State as a Function of V_{CCI} and V_{CC} Voltage Levels

Figure 2-2 • V2 Devices – I/O State as a Function of V_{CCI} and V_{CC} Voltage Levels

Thermal Characteristics

Introduction

The temperature variable in the Actel Designer software refers to the junction temperature, not the ambient temperature. This is an important distinction because dynamic and static power consumption cause the chip junction temperature to be higher than the ambient temperature.

EQ 2-1 can be used to calculate junction temperature.

$$T_J = \text{Junction Temperature} = \Delta T + T_A$$

EQ 2-1

where:

T_A = Ambient temperature

ΔT = Temperature gradient between junction (silicon) and ambient $\Delta T = \theta_{ja} * P$

θ_{ja} = Junction-to-ambient of the package. θ_{ja} numbers are located in Figure 2-5.

P = Power dissipation

Package Thermal Characteristics

The device junction-to-case thermal resistivity is θ_{jc} and the junction-to-ambient air thermal resistivity is θ_{ja} . The thermal characteristics for θ_{ja} are shown for two air flow rates. The maximum operating junction temperature is 100°C. EQ 2-2 shows a sample calculation of the maximum operating power dissipation allowed for a 484-pin FBGA package at commercial temperature and in still air.

$$\text{Maximum Power Allowed} = \frac{\text{Max. junction temp. (}^\circ\text{C)} - \text{Max. ambient temp. (}^\circ\text{C)}}{\theta_{ja} (^\circ\text{C/W)}} = \frac{100^\circ\text{C} - 70^\circ\text{C}}{20.5^\circ\text{C/W}} = 1.46 \text{ W}$$

EQ 2-2

Table 2-5 • Package Thermal Resistivities

Package Type	Pin Count	θ_{jc}	θ_{ja}			Units
			Still Air	200 ft./min.	500 ft./min.

Calculating Power Dissipation

Quiescent Supply Current

Quiescent supply current (I_{DD}) calculation depends on multiple factors, including operating voltages (V_{CC} , V_{CCI} , and V_{JTAG}), operating temperature, system clock frequency, and power mode usage. Actel recommends using the Power Calculator and SmartPower software estimation tools to evaluate the projected static and active power based on the user design, power mode usage, operating voltage, and temperature.

Table 2-8 • Quiescent Supply Current (I_{DD}) Characteristics, IGLOO nano Flash*Freeze Mode*

	Core Voltage	AGLN010	AGLN015	AGLN020	AGLN060	AGLN125	AGLN250	Units
Typical (25°C)	1.2 V	1.7	3.3	3.3	8	13	20	μA
	1.5 V	3	6	6	10	18	34	μA

* I_{DD} includes V_{CC} , V_{PUMP} , V_{CCI} , V_{JTAG} , and V_{CCPLL} currents.

Table 2-9 • Quiescent Supply Current (I_{DD}) Characteristics, IGLOO nano Sleep Mode ($V_{CC} = 0\text{ V}$)*

	Core Voltage	AGLN010	AGLN015	AGLN020	AGLN060	AGLN125	AGLN250	Units
$V_{CCI}/V_{JTAG} = 1.2\text{ V}$ (per bank) Typical (25°C)	1.2 V	1.7	1.7	1.7	1.7	1.7	1.7	μA

P _{AC5}	First contribution of a VersaTile used as a sequential module	0.045					
P _{AC6}	Second contribution of a VersaTile used as a sequential module	0.186					
P _{AC7}	Contribution of a VersaTile used as a combinatorial module	0.11					
P _{AC8}	Average contribution of a routing net	0.45					
P _{AC9}	Contribution of an I/O input pin (standard-dependent)	See Table 2-12 on page 2-9					
P _{AC10}	Contribution of an I/O output pin (standard-dependent)	See Table 2-13 on page 2-9					
P _{AC11}	Average contribution of a RAM block during a read operation	25.00			N/A		
P _{AC12}	Average contribution of a RAM block during a write operation	30.00			N/A		
P _{AC13}	Dynamic contribution for PLL	2.10			N/A		

Table 2-17 • Different Components Contributing to the Static Power Consumption in IGLOO nano Devices For IGLOO nano V2 Devices, 1.2 V Core Supply Voltage

Parameter	Definition	Device-Specific Static Power (mW)					
		AGLN250	AGLN125	AGLN060	AGLN020	AGLN015	AGLN010
P _{DC1}	Array static power in Active mode	See Table 2-11 on page 2-8					
P _{DC2}	Array static power in Static (Idle) mode	See Table 2-11 on page 2-8					
P _{DC3}	Array static power in Flash*Freeze mode	See Table 2-8 on page 2-7					
P _{DC4} ²	Static PLL contribution	0.90			N/A		
P _{DC5}	Bank quiescent power (V _{CCI} -dependent)	See Table 2-11 on page 2-8					

Notes:

1. For a different output load, drive strength, or slew rate, Actel recommends using the Actel power spreadsheet calculator or the SmartPower tool in Actel Libero IDE.
2. Minimum contribution of the PLL when running at lowest frequency.

Power Calculation Methodology

This section describes a simplified method to estimate power consumption of an application. For more accurate and detailed power estimations, use the SmartPower tool in Actel Libero IDE software.

The power calculation methodology described below uses the following variables:

- The number of PLLs as well as the number and the frequency of each output clock generated
- The number of combinatorial and sequential cells used in the design
- The internal clock frequencies
- The number and the standard of I/O pins used in the design
- The number of RAM blocks used in the design
- Toggle rates of I/O pins as well as VersaTiles—guidelines are provided in [Table 2-18 on page 2-14](#).
- Enable rates of output buffers—guidelines are provided for typical applications in [Table 2-19 on page 2-14](#).
- Read rate and write rate to the memory—guidelines are provided for typical applications in [Table 2-19 on page 2-14](#). The calculation should be repeated for each clock domain defined in the design.

Methodology

Total Power Consumption— P_{TOTAL}

$$P_{TOTAL} = P_{STAT} + P_{DYN}$$

P_{STAT} is the total static power consumption.

P_{DYN} is the total dynamic power consumption.

Total Static Power Consumption— P_{STAT}

$$P_{STAT} = (P_{DC1} \text{ or } P_{DC2} \text{ or } P_{DC3}) + N_{BANKS} * P_{DC5}$$

N_{BANKS} is the number of I/O banks powered in the design.

Total Dynamic Power Consumption— P_{DYN}

$$P_{DYN} = P_{CLOCK} + P_{S-CELL} + P_{C-CELL} + P_{NET} + P_{INPUTS} + P_{OUTPUTS} + P_{MEMORY} + P_{PLL}$$

Global Clock Contribution— P_{CLOCK}

$$P_{CLOCK} = (P_{AC1} + N_{SPINE} * P_{AC2} + N_{ROW} * P_{AC3} + N_{S-CELL} * P_{AC4}) * F_{CLK}$$

N_{SPINE} is the number of global spines used in the user design—guidelines are provided in [Table 2-18 on page 2-14](#).

N_{ROW} is the number of VersaTile rows used in the design—guidelines are provided in [Table 2-18 on page 2-14](#).

F_{CLK} is the global clock signal frequency.

N_{S-CELL} is the number of VersaTiles used as sequential modules in the design.

P_{AC1} , P_{AC2} , P_{AC3} , and P_{AC4} are device-dependent.

Sequential Cells Contribution— P_{S-CELL}

$$P_{S-CELL} = N_{S-CELL} * (P_{AC5} + \alpha_1 / 2 * P_{AC6}) * F_{CLK}$$

N_{S-CELL} is the number of VersaTiles used as sequential modules in the design. When a multi-tile sequential cell is used, it should be accounted for as 1.

α_1 is the toggle rate of VersaTile outputs—guidelines are provided in [Table 2-18 on page 2-14](#).

F_{CLK} is the global clock signal frequency.

Combinatorial Cells Contribution— P_{C-CELL}

$$P_{C-CELL} = N_{C-CELL} * \alpha_1 / 2 * P_{AC7} * F_{CLK}$$

N_{C-CELL} is the number of VersaTiles used as combinatorial modules in the design.

α_1 is the toggle rate of VersaTile outputs—guidelines are provided in [Table 2-18 on page 2-14](#).

F_{CLK} is the global clock signal frequency.

Routing Net Contribution— P_{NET}

$$P_{NET} = (N_{S-CELL} + N_{C-CELL}) * \alpha_1 / 2 * P_{AC8} * F_{CLK}$$

N_{S-CELL} is the number of VersaTiles used as sequential modules in the design.

N_{C-CELL} is the number of VersaTiles used as combinatorial modules in the design.

α_1 is the toggle rate of VersaTile outputs—guidelines are provided in [Table 2-18 on page 2-14](#).

F_{CLK} is the global clock signal frequency.

I/O Input Buffer Contribution— P_{INPUTS}

$$P_{INPUTS} = N_{INPUTS} * \alpha_2 / 2 * P_{AC9} * F_{CLK}$$

N_{INPUTS} is the number of I/O input buffers used in the design.

α_2 is the I/O buffer toggle rate—guidelines are provided in [Table 2-18 on page 2-14](#).

F_{CLK} is the global clock signal frequency.

I/O Output Buffer Contribution— $P_{OUTPUTS}$

$$P_{OUTPUTS} = N_{OUTPUTS} * \alpha_2 / 2 * \beta_1 * P_{AC10} * F_{CLK}$$

$N_{OUTPUTS}$ is the number of I/O output buffers used in the design.

α_2 is the I/O buffer toggle rate—guidelines are provided in [Table 2-18 on page 2-14](#).

β_1 is the I/O buffer enable rate—guidelines are provided in [Table 2-19 on page 2-14](#).

F_{CLK} is the global clock signal frequency.

RAM Contribution— P_{MEMORY}

$$P_{MEMORY} = P_{AC11} * N_{BLOCKS} * F_{READ-CLOCK} * \beta_2 + P_{AC12} * N_{BLOCK} * F_{WRITE-CLOCK} * \beta_3$$

N_{BLOCKS} is the number of RAM blocks used in the design.

$F_{READ-CLOCK}$ is the memory read clock frequency.

β_2 is the RAM enable rate for read operations.

$F_{WRITE-CLOCK}$ is the memory write clock frequency.

β_3 is the RAM enable rate for write operations—guidelines are provided in [Table 2-19 on page 2-14](#).

PLL Contribution— P_{PLL}

$$P_{PLL} = P_{DC4} + P_{AC13} * F_{CLKOUT}$$

F_{CLKOUT} is the output clock frequency.¹

1. If a PLL is used to generate more than one output clock, include each output clock in the formula by adding its corresponding contribution ($P_{AC13} * F_{CLKOUT}$ product) to the total PLL contribution.

Guidelines

Toggle Rate Definition

A toggle rate defines the frequency of a net or logic element relative to a clock. It is a percentage. If the toggle rate of a net is 100%, this means that this net switches at half the clock frequency. Below are some examples:

- The average toggle rate of a shift register is 100% because all flip-flop outputs toggle at half of the clock frequency.
- The average toggle rate of an 8-bit counter is 25%:
 - Bit 0 (LSB) = 100%
 - Bit 1 = 50%
 - Bit 2 = 25%
 - ...
 - Bit 7 (MSB) = 0.78125%
 - Average toggle rate = $(100\% + 50\% + 25\% + 12.5\% + \dots + 0.78125\%) / 8$

Enable Rate Definition

Output enable rate is the average percentage of time during which tristate outputs are enabled. When nontristate output buffers are used, the enable rate should be 100%.

Table 2-18 • Toggle Rate Guidelines Recommended for Power Calculation

Component	Definition	Guideline
α_1	Toggle rate of VersaTile outputs	10%
α_2	I/O buffer toggle rate	10%

Table 2-19 • Enable Rate Guidelines Recommended for Power Calculation

Component	Definition	Guideline
β_1	I/O output buffer enable rate	100%
β_2	RAM enable rate for read operations	12.5%
β_3	RAM enable rate for write operations	12.5%

User I/O Characteristics

Timing Model

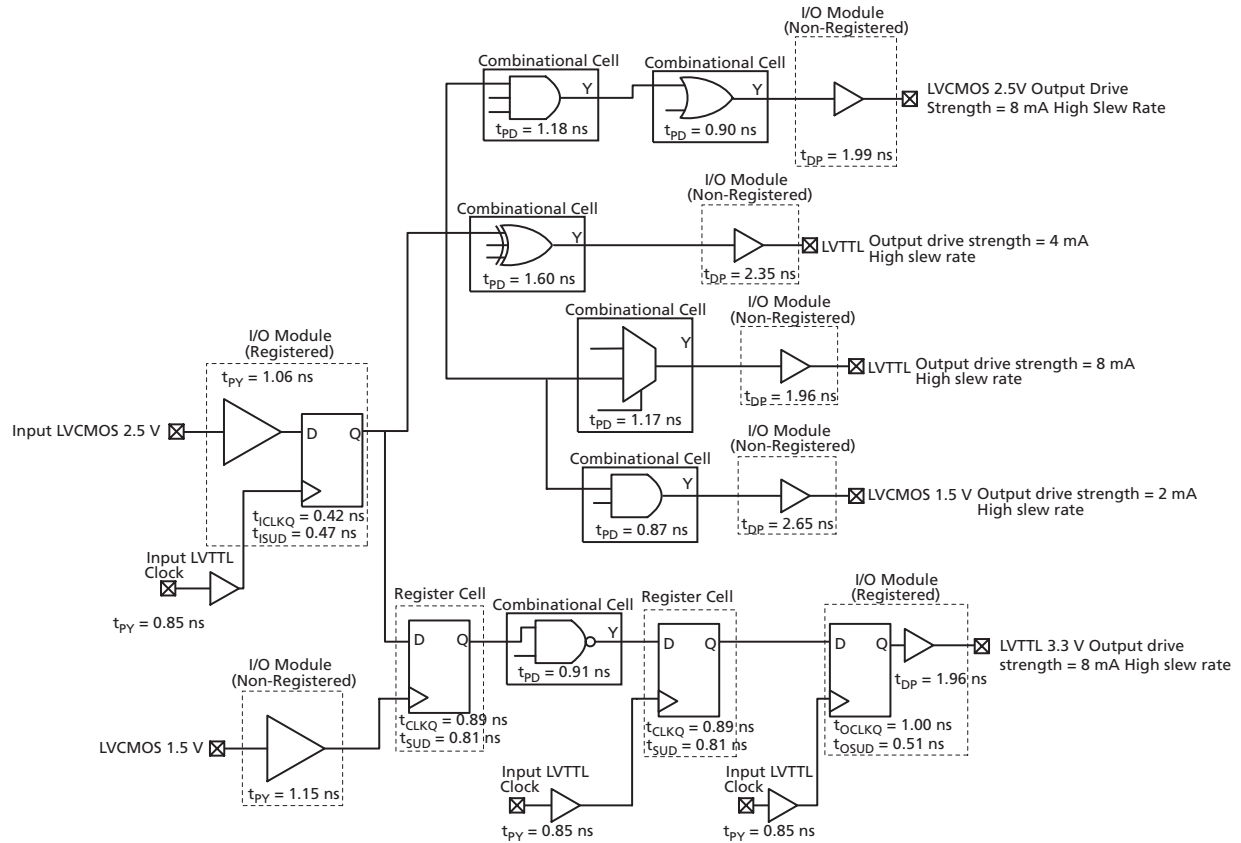

Figure 2-3 • Timing Model

Operating Conditions: STD Speed, Commercial Temperature Range ($T_J = 70^\circ\text{C}$), Worst-Case $V_{CC} = 1.425$ V, for DC 1.5 V Core Voltage, Applicable to V2 and V5 Devices

1.2 V LVCMOS ³	1 mA	High	-0.3	0.35 * V _{CC1}	0.65 * V _{CC1}	3.6	0.25 * V _{CC1}	0.75 * V _{CC1}	1	1
1.2 V LVCMOS Wide Range ³	Any ⁴	High	-0.3	0.3 * V _{CC1}	0.7 * V _{CC1}	3.6	0.1	V _{CC1} - 0.1	100 μA	100 μA

Notes:

1. Currents are measured at 85°C junction temperature.
2. All LVCMOS 3.3 V software macros support LVCMOS 3.3 V wide range, as specified in the JESD8-B specification.
3. Applicable to IGLOO nano V2 devices operating at V_{CC1} ≥ V_{CC}.
4. All LVCMOS 1.2 V software macros support LVCMOS 1.2 V wide range, as specified in the JESD8-12 specification.

**Table 2-21 • Summary of Maximum and Minimum DC Input Levels
Applicable to Commercial and Industrial Conditions**

DC I/O Standards	Commercial ¹		Industrial ²	
	I _{IL} ³	I _{IH} ⁴	I _{IL} ³	I _{IH} ⁴
	μA	μA	μA	μA
3.3 V LVTTTL / 3.3 V LVCMOS	10	10	15	15
3.3 V LVCOMS Wide Range	10	10	15	15
2.5 V LVCMOS	10	10	15	15
1.8 V LVCMOS	10	10	15	15
1.5 V LVCMOS	10	10	15	15
1.2 V LVCMOS ⁵	10	10	15	15
1.2 V LVCMOS Wide Range ⁵	10	10	15	15

Notes:

1. Commercial range (-20°C < T_A < 70°C)
2. Industrial range (-40°C < T_A < 85°C)
3. I_{IH} is the input leakage current per I/O pin over recommended operating conditions, where V_{IH} < V_{IN} < V_{CC1}. Input current is larger when operating outside recommended ranges.
4. I_{IL} is the input leakage current per I/O pin over recommended operating conditions, where -0.3 V < V_{IN} < V_{IL}.
5. Applicable to IGLOO nano V2 devices operating at V_{CC1} ≥ V_{CC}.

Summary of I/O Timing Characteristics – Default I/O Software Settings

Table 2-22 • Summary of AC Measuring Points

Standard	Measuring Trip Point (V_{trip})
3.3 V LVTTTL / 3.3 V LVCMOS	1.4 V

Symbol	Definition	Conditions	Min.	Max.	Units
C_{IN}	Input capacitance	$V_{IN} = 0, f = 1.0 \text{ MHz}$		8	pF
C_{INCLK}	Input capacitance on the clock pin	$V_{IN} = 0, f = 1.0 \text{ MHz}$		8	pF

Table 2-27 • I/O Output Buffer Maximum Resistances ¹

Standard	Drive Strength	$R_{PULL-DOWN}$ (Ω) ²	$R_{PULL-UP}$ (Ω) ³
3.3 V LVTTTL / 3.3V LVCMOS	2 mA	100	300
	4 mA	100	300
	6 mA	50	150
	8 mA	50	150
3.3 V LVCMOS Wide Range	100 μ A	TBD	TBD
2.5 V LVCMOS	2 mA	100	200
	4 mA	100	200
	6 mA	50	100
	8 mA	50	100
1.8 V LVCMOS	2 mA	200	225
	4 mA	100	112
1.5 V LVCMOS	2 mA	200	224
1.2 V LVCMOS ⁴	2 mA	TBD	TBD
1.2 V LVCMOS Wide Range ⁴	100 μ A	TBD	TBD

Notes:

1. These maximum values are provided for informational reasons only. Minimum output buffer resistance values depend on V_{CC} , drive strength selection, temperature, and process. For board design considerations and detailed output buffer resistances, use the corresponding IBIS models located on the Actel website at <http://www.actel.com/download/libis/default.aspx>.
2. $R_{(PULL-DOWN-MAX)} = (V_{OLspec}) / I_{OLspec}$
3. $R_{(PULL-UP-MAX)} = (V_{CCImax} - V_{OHspec}) / I_{OHspec}$
4. Applicable to IGLOO nano V2 devices operating at $V_{CCI} \geq V_{CC}$.

Table 2-28 • I/O Weak Pull-Up/Pull-Down Resistances
 Minimum and Maximum Weak Pull-Up/Pull-Down Resistance Values

V _{CCI}	R _(WEAK PULL-UP) ¹ (Ω)		R _(WEAK PULL-DOWN) ² (Ω)	
	Min.	Max.	Min.	Max.
3.3 V	10 k	45 k	10 k	45 k
2.5 V	11 k	55 k	12 k	74 k
1.8 V	18 k	70 k	17 k	110 k
1.5 V	19 k	90 k	19 k	140 k
1.2 V	25 k	110 k	25 k	150 k

Notes:

1. $R_{(WEAK\ PULL-UP-MAX)} = (V_{OLspec}) / I_{(WEAK\ PULL-UP-MIN)}$
2. $R_{(WEAK\ PULL-UP-MAX)} = (V_{CCImax} - V_{OHspec}) / I_{(WEAK\ PULL-UP-MIN)}$

Table 2-29 • I/O Short Currents I_{OSH}/I_{OSL}

	Drive Strength	I _{OSL} (mA)*	I _{OSH} (mA)*
3.3 V LVTTTL / 3.3 V LVCMOS	2 mA	25	27
	4 mA	25	27
	6 mA	51	54
	8 mA	51	54
3.3 V LVCMOS Wide Range	100 μA	TBD	TBD
2.5 V LVCMOS	2 mA	16	18
	4 mA	16	18
	6 mA	32	37
	8 mA	32	37
1.8 V LVCMOS	2 mA	9	11
	4 mA	17	22
1.5 V LVCMOS	2 mA	13	16
1.2 V LVCMOS	1 mA	TBD	TBD
1.2 V LVCMOS Wide Range	100 μA	TBD	TBD

 * T_J = 100°C

The length of time an I/O can withstand I_{OSH}/I_{OSL} events depends on the junction temperature. The reliability data below is based on a 3.3 V, 8 mA I/O setting, which is the worst case for this type of analysis.

For example, at 110°C, the short current condition would have to be sustained for more than three months to cause a reliability concern. The I/O design does not contain any short circuit protection, but such protection would only be needed in extremely prolonged stress conditions.

Table 2-30 • Duration of Short Circuit Event before Failure

Temperature	Time before Failure
-40°C	> 20 years
-20°C	> 20 years
0°C	> 20 years
25°C	> 20 years
70°C	5 years
85°C	2 years
100°C	6 months
110°C	3 months

Table 2-31 • Schmitt Trigger Input Hysteresis Hysteresis Voltage Value (Typ.) for Schmitt Mode Input Buffers

Input Buffer Configuration	Hysteresis Value (typ.)
3.3 V LVTTTL / LVCMOS (Schmitt trigger mode)	240 mV
2.5 V LVCMOS (Schmitt trigger mode)	140 mV
1.8 V LVCMOS (Schmitt trigger mode)	80 mV
1.5 V LVCMOS (Schmitt trigger mode)	60 mV
1.2 V LVCMOS (Schmitt trigger mode)	40 mV

Table 2-32 • I/O Input Rise Time, Fall Time, and Related I/O Reliability

Input Buffer	Input Rise/Fall Time (min.)	Input Rise/Fall Time (max.)	Reliability
LVTTTL/LVCMOS (Schmitt trigger disabled)	No requirement	10 ns *	20 years (100°C)
LVTTTL/LVCMOS (Schmitt trigger enabled)	No requirement	No requirement, but input noise voltage cannot exceed Schmitt hysteresis.	20 years (100°C)

* The maximum input rise/fall time is related to the noise induced into the input buffer trace. If the noise is low, then the rise time and fall time of input buffers can be increased beyond the maximum value. The longer the rise/fall times, the more susceptible the input signal is to the board noise. Actel recommends signal integrity evaluation/characterization of the system to ensure that there is no excessive noise coupling into input signals.

Single-Ended I/O Characteristics

3.3 V LVTTTL / 3.3 V LVCMOS

Low-Voltage Transistor–Transistor Logic (LVTTTL) is a general-purpose standard (EIA/JESD) for 3.3 V applications. It uses an LVTTTL input buffer and push-pull output buffer.

Table 2-33 • Minimum and Maximum DC Input and Output Levels

3.3 V LVTTTL / 3.3 V LVCMOS	V_{IL}		V_{IH}		V_{OL}	V_{OH}	I_{OL}	I_{OH}	I_{OSL}	I_{OSH}	I_{IL}^1	I_{IH}^2
	Min., V	Max., V	Min., V	Max., V	Max., V	Min., V	mA	mA	Max., mA ³	Max., mA ³	μA^4	μA^4
2 mA	-0.3	0.8	2	3.6	0.4	2.4	2	2	25	27	10	10
4 mA	-0.3	0.8	2	3.6	0.4	2.4	4	4	25	27	10	10
6 mA	-0.3	0.8	2	3.6	0.4	2.4	6	6	51	54	10	10
8 mA	-0.3	0.8	2	3.6	0.4	2.4	8	8	51	54	10	10

Notes:

1. I_{IL} is the input leakage current per I/O pin over recommended operating conditions where $-0.3 < V_{IN} < V_{IL}$.
2. I_{IH} is the input leakage current per I/O pin over recommended operating conditions where $V_{IH} < V_{IN} < V_{CCI}$. Input current is larger when operating outside recommended ranges.
3. Currents are measured at high temperature (100°C junction temperature) and maximum voltage.
4. Currents are measured at 85°C junction temperature.
5. Software default selection highlighted in gray.

3.3 V LVCMOS Wide Range

Table 2-39 • Minimum and Maximum DC Input and Output Levels for LVCMOS 3.3 V Wide Range

3.3 V LVCMOS Wide Range	V_{IL}		V_{IH}		V_{OL}	V_{OH}	I_{OL}	I_{OH}	I_{IL}^1	I_{IH}^2
	Min., V	Max., V	Min., V	Max., V	Max., V	Min., V	μA	μA	μA^3	μA^3
All ⁴	-0.3	0.8	2	3.6	0.2	$V_{DD} - 0.2$	100	100	10	10

Notes:

1. I_{IL} is the input leakage current per I/O pin over recommended operating conditions where $-0.3 < V_{IN} < V_{IL}$.
2. I_{IH} is the input leakage current per I/O pin over recommended operating conditions where $V_{IH} < V_{IN} < V_{CCI}$. Input current is larger when operating outside recommended ranges.
3. Currents are measured at 85°C junction temperature.
4. All LVCMOS 3.3 V software macros support LVCMOS 3.3 V Wide Range, as specified in the JEDEC JESD8-B specification.

2.5 V LVCMOS

Low-Voltage CMOS for 2.5 V is an extension of the LVCMOS standard (JESD8-5) used for general-purpose 2.5 V applications. It uses a 5 V-tolerant input buffer and push-pull output buffer.

Table 2-40 • Minimum and Maximum DC Input and Output Levels

2.5 V LVCMOS Drive Strength	V_{IL}		V_{IH}		V_{OL}	V_{OH}	I_{OL}	I_{OH}	I_{OSL}	I_{OSH}	I_{IL}^1	I_{IH}^2

2. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

1.5 V LVCMOS (JESD8-11)

Low-Voltage CMOS for 1.5 V is an extension of the LVCMOS standard (JESD8-5) used for general-purpose 1.5 V applications. It uses a 1.5 V input buffer and a push-pull output buffer.

Table 2-52 • Minimum and Maximum DC Input and Output Levels

1.5 V LVCMOS	V_{IL}		V_{IH}		V_{OL}	V_{OH}	I_{OL}	I_{OH}	I_{OSL}	I_{OSH}	I_{IL}^1	I_{IH}^2
	Min., V	Max., V	Min., V	Max., V	Max., V	Min., V	mA	mA	Max., mA ³	Max., mA ³	μA^4	μA^4
2 mA	-0.3	0.35 * V_{CC1}	0.65 * V_{CC1}	3.6	0.25 * V_{CC1}	0.75 * V_{CC1}	2	2	13	16	10	10

Notes:

1. I_{IL} is the input leakage current per I/O pin over recommended operating conditions where $-0.3 < V_{IN} < V_{IL}$.
2. I_{IH} is the input leakage current per I/O pin over recommended operating conditions where $V_{IH} < V_{IN} < V_{CC1}$. Input current is larger when operating outside recommended ranges.
3. Currents are measured at high temperature (100°C junction temperature) and maximum voltage.
4. Currents are measured at 85°C junction temperature.
5. Software default selection highlighted in gray.

Figure 2-10 • AC Loading

Table 2-53 • 1.5 V LVCMOS AC Waveforms, Measuring Points, and Capacitive Loads

Input LOW (V)	Input HIGH (V)	Measuring Point* (V)	C_{LOAD} (pF)
0	1.5	0.75	5

* Measuring point = V_{trip} . See Table 2-22 on page 2-20 for a complete table of trip points.

Timing Characteristics

Applies to 1.5 V DC Core Voltage

Table 2-54 • 1.5 V LVCMOS Low Slew – Applies to 1.5 V DC Core Voltage
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, Worst-Case $V_{CC} = 1.425\text{ V}$, Worst-Case $V_{CCI} = 1.4\text{ V}$

Drive Strength	Speed Grade	t_{DOUT}	t_{DP}	t_{DIN}	t_{PY}	t_{PYS}	t_{EOUT}	t_{ZL}	t_{ZH}	t_{LZ}	t_{HZ}	Units

Notes:

1. Software default selection highlighted in gray.
2. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

Applies to 1.2 V DC Core Voltage

Table 2-56 • 1.5 V LVCMOS Low Slew – Applies to 1.2 V DC Core Voltage
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, Worst-Case $V_{CC} = 1.14\text{ V}$, Worst-Case $V_{CCI} = 1.4\text{ V}$

Drive Strength	Speed Grade	t_{DOUT}	t_{DP}	t_{DIN}	t_{PY}	t_{PYS}	t_{EOUT}	t_{ZL}	t_{ZH}	t_{LZ}	t_{HZ}	Units
2 mA	STD	1.55	7.23	0.26	1.26	1.62	1.10	6.61	5.94	2.53	2.58	ns

Note: For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

Table 2-57 • 1.5 V LVCMOS High Slew – Applies to 1.2 V DC Core Voltage
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, Worst-Case $V_{CC} = 1.14\text{ V}$, Worst-Case $V_{CCI} = 1.4\text{ V}$

Drive Strength	Speed Grade	t_{DOUT}	t_{DP}	t_{DIN}	t_{PY}	t_{PYS}	t_{EOUT}	t_{ZL}	t_{ZH}	t_{LZ}	t_{HZ}	Units
2 mA	STD	1.55	3.50	0.26	1.26	1.62	1.10	3.09	2.76	2.53	2.67	ns

Notes:

1. Software default selection highlighted in gray.
2. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

1.2 V LVCMOS (JESD8-12A)

Low-Voltage CMOS for 1.2 V complies with the LVCMOS standard JESD8-12A for general purpose 1.2 V applications. It uses a 1.2 V input buffer and a push-pull output buffer.

Table 2-58 • Minimum and Maximum DC Input and Output Levels

1.2 V LVCMOS	V_{IL}		V_{IH}		V_{OL}	V_{OH}	I_{OL}	I_{OH}	I_{OSL}	I_{OSH}	I_{IL}^1	I_{IH}^2
Drive Strength	Min., V	Max., V	Min., V	Max., V	Max., V	Min., V	mA	mA	Max., mA ³	Max., mA ³	μA^4	μA^4
1 mA	-0.3	$0.35 * V_{CC1}$	$0.65 * V_{CC1}$	3.6	$0.25 * V_{CC1}$	$0.75 * V_{CC1}$	1	1	TBD	TBD	10	10

Notes:

- I_{IL} is the input leakage current per I/O pin over recommended operating conditions where $-0.3 < V_{IN} < V_{IL}$.
- I_{IH} is the input leakage current per I/O pin over recommended operating conditions where $V_{IH} < V_{IN} < V_{CC1}$. Input current is larger when operating outside recommended ranges.
- Currents are measured at high temperature (100°C junction temperature) and maximum voltage.
- Currents are measured at 85°C junction temperature.
- Software default selection highlighted in gray.

t_{WCLR}	Asynchronous Clear Minimum Pulse Width for the Core Register	0.30	ns
t_{WPRE}	Asynchronous Preset Minimum Pulse Width for the Core Register	0.30	ns
t_{CKMPWH}	Clock Minimum Pulse Width HIGH for the Core Register	0.56	ns
t_{CKMPWL}	Clock Minimum Pulse Width LOW for the Core Register	0.56	ns

Note: For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

1.2 V DC Core Voltage

Table 2-79 • Register Delays

 Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, Worst-Case $V_{CC} = 1.14\text{ V}$

Parameter	Description	Std.	Units
t_{CLKQ}	Clock-to-Q of the Core Register	1.61	ns
t_{SUD}	Data Setup Time for the Core Register	1.17	ns
t_{HD}	Data Hold Time for the Core Register	0.00	ns
t_{SUE}	Enable Setup Time for the Core Register	1.29	ns
t_{HE}	Enable Hold Time for the Core Register	0.00	ns
t_{CLR2Q}	Asynchronous Clear-to-Q of the Core Register	0.87	ns
t_{PRE2Q}	Asynchronous Preset-to-Q of the Core Register	0.89	ns
t_{REMCLR}	Asynchronous Clear Removal Time for the Core Register	0.00	ns
t_{RECCLR}	Asynchronous Clear Recovery Time for the Core Register	0.24	ns
t_{REMPRE}	Asynchronous Preset Removal Time for the Core Register	0.00	ns
t_{RECPRE}	Asynchronous Preset Recovery Time for the Core Register	0.24	ns
t_{WCLR}	Asynchronous Clear Minimum Pulse Width for the Core Register	0.46	ns
t_{WPRE}	Asynchronous Preset Minimum Pulse Width for the Core Register	0.46	ns
t_{CKMPWH}	Clock Minimum Pulse Width HIGH for the Core Register	0.95	ns
t_{CKMPWL}	Clock Minimum Pulse Width LOW for the Core Register	0.95	ns

Note: For specific junction temperature and voltage supply levels, refer to [Table 2-7 on page 2-7](#) for derating values.

Global Resource Characteristics

AGLN125 Clock Tree Topology

Clock delays are device-specific. Figure 2-25 is an example of a global tree used for clock routing. The global tree presented in Figure 2-25 is driven by a CCC located on the west side of the AGLN125 device. It is used to drive all D-flip-flops in the device.

Figure 2-25 • Example of Global Tree Use in an AGLN125 Device for Clock Routing

Global Tree Timing Characteristics

Global clock delays include the central rib delay, the spine delay, and the row delay. Delays do not include I/O input buffer clock delays, as these are I/O standard-dependent, and the clock may be driven and conditioned internally by the CCC module. For more details on clock conditioning capabilities, refer to the "Clock Conditioning Circuits" section on page 2-66. Table 2-80 to Table 2-88 on page 2-64 present minimum and maximum global clock delays within each device. Minimum and maximum delays are measured with minimum and maximum loading.

Timing Characteristics

1.5 V DC Core Voltage

Table 2-80 • AGLN010 Global Resource
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, $V_{CC} = 1.425\text{ V}$

Parameter	Description	Std.		Units
		Min. ¹	Max. ²	
t_{RCKL}	Input LOW Delay for Global Clock	1.08	1.36	ns
t_{RCKH}	Input HIGH Delay for Global Clock	1.09	1.44	ns
$t_{RCKMPWH}$	Minimum Pulse Width HIGH for Global Clock			ns
$t_{RCKMPWL}$	Minimum Pulse Width LOW for Global Clock			ns
t_{RCKSW}	Maximum Skew for Global Clock		0.35	ns
F_{RMAX}	Maximum Frequency for Global Clock			MHz

Notes:

1. Value reflects minimum load. The delay is measured from the CCC output to the clock pin of a sequential element, located in a lightly loaded row (single element is connected to the global net).
2. Value reflects maximum load. The delay is measured on the clock pin of the farthest sequential element, located in a fully loaded row (all available flip-flops are connected to the global net in the row).
3. For specific junction temperature and voltage supply levels, refer to Table 2-6 on page 2-6 for derating values.

Table 2-81 • AGLN015 Global Resource
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, $V_{CC} = 1.425\text{ V}$

Parameter	Description	Std.		Units
		Min. ¹	Max. ²	
t_{RCKL}	Input LOW Delay for Global Clock	1.15	1.49	ns
t_{RCKH}	Input HIGH Delay for Global Clock	1.16	1.59	ns
$t_{RCKMPWH}$	Minimum Pulse Width HIGH for Global Clock			ns
$t_{RCKMPWL}$	Minimum Pulse Width LOW for Global Clock			ns
t_{RCKSW}	Maximum Skew for Global Clock		0.42	ns
F_{RMAX}	Maximum Frequency for Global Clock			MHz

Notes:

1. Value reflects minimum load. The delay is measured from the CCC output to the clock pin of a sequential element, located in a lightly loaded row (single element is connected to the global net).
2. Value reflects maximum load. The delay is measured on the clock pin of the farthest sequential element, located in a fully loaded row (all available flip-flops are connected to the global net in the row).
3. For specific junction temperature and voltage supply levels, refer to Table 2-6 on page 2-6 for derating values.

Table 2-82 • AGLN020 Global Resource
 Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, $V_{CC} = 1.425\text{ V}$

Parameter	Description	Std.		Units
		Min. ¹	Max. ²	
t_{RCKL}	Input LOW Delay for Global Clock	1.15	1.49	ns
t_{RCKH}	Input HIGH Delay for Global Clock	1.16	1.59	ns
$t_{RCKMPWH}$	Minimum Pulse Width HIGH for Global Clock			ns
$t_{RCKMPWL}$	Minimum Pulse Width LOW for Global Clock			ns
t_{RCKSW}	Maximum Skew for Global Clock		0.42	ns
F_{RMAX}	Maximum Frequency for Global Clock			MHz

Notes:

1. Value reflects minimum load. The delay is measured from the CCC output to the clock pin of a sequential element, located in a lightly loaded row (single element is connected to the global net).
2. Value reflects maximum load. The delay is measured on the clock pin of the farthest sequential element, located in a fully loaded row (all available flip-flops are connected to the global net in the row).
3. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

Table 2-83 • AGLN060 Global Resource
 Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, $V_{CC} = 1.425\text{ V}$

Parameter	Description	Std.		Units
		Min. ¹	Max. ²	
t_{RCKL}	Input LOW Delay for Global Clock	1.32	1.67	ns
t_{RCKH}	Input HIGH Delay for Global Clock	1.34	1.76	ns
$t_{RCKMPWH}$	Minimum Pulse Width HIGH for Global Clock			ns
$t_{RCKMPWL}$	Minimum Pulse Width LOW for Global Clock			ns
t_{RCKSW}	Maximum Skew for Global Clock		0.42	ns
F_{RMAX}	Maximum Frequency for Global Clock			MHz

Notes:

1. Value reflects minimum load. The delay is measured from the CCC output to the clock pin of a sequential element, located in a lightly loaded row (single element is connected to the global net).
2. Value reflects maximum load. The delay is measured on the clock pin of the farthest sequential element, located in a fully loaded row (all available flip-flops are connected to the global net in the row).
3. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

Table 2-84 • AGLN125 Global Resource
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, $V_{CC} = 1.425\text{ V}$

Parameter	Description	Std.		Units
		Min. ¹	Max. ²	
t_{RCKL}	Input LOW Delay for Global Clock	1.36	1.71	ns
t_{RCKH}	Input HIGH Delay for Global Clock	1.39	1.82	ns
$t_{RCKMPWH}$	Minimum Pulse Width HIGH for Global Clock			ns
$t_{RCKMPWL}$	Minimum Pulse Width LOW for Global Clock			ns
t_{RCKSW}	Maximum Skew for Global Clock		0.43	ns
F_{RMAX}	Maximum Frequency for Global Clock			MHz

Notes:

1. Value reflects minimum load. The delay is measured from the CCC output to the clock pin of a sequential element, located in a lightly loaded row (single element is connected to the global net).
2. Value reflects maximum load. The delay is measured on the clock pin of the farthest sequential element, located in a fully loaded row (all available flip-flops are connected to the global net in the row).
3. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

Table 2-85 • AGLN250 Global Resource
Commercial-Case Conditions: $T_J = 70^\circ\text{C}$, $V_{CC} = 1.425\text{ V}$

Parameter	Description	Std.		Units
		Min. ¹	Max. ²	
t_{RCKL}	Input LOW Delay for Global Clock	1.39	1.73	ns
t_{RCKH}	Input HIGH Delay for Global Clock	1.41	1.84	ns
$t_{RCKMPWH}$	Minimum Pulse Width HIGH for Global Clock			ns
$t_{RCKMPWL}$	Minimum Pulse Width LOW for Global Clock			ns
t_{RCKSW}	Maximum Skew for Global Clock		0.43	ns
F_{RMAX}	Maximum Frequency for Global Clock			MHz

Notes:

1. Value reflects minimum load. The delay is measured from the CCC output to the clock pin of a sequential element, located in a lightly loaded row (single element is connected to the global net).
2. Value reflects maximum load. The delay is measured on the clock pin of the farthest sequential element, located in a fully loaded row (all available flip-flops are connected to the global net in the row).
3. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

1.2 V DC Core Voltage

Clock Conditioning Circuits

CCC Electrical Specifications

Timing Characteristics

Table 2-92 • IGLOO nano CCC/PLL Specification
For IGLOO nano V2 or V5 devices, 1.5 V DC Core Supply Voltage

Parameter	Min.	Typ.	Max.	Units
Clock Conditioning Circuitry Input Frequency f_{IN_CCC}	1.5		250	MHz
Clock Conditioning Circuitry Output Frequency f_{OUT_CCC}	0.75		250	MHz
Delay Increments in Programmable Delay Blocks ^{1, 2}		360		ps
Number of Programmable Values in Each Programmable Delay Block			32	
Serial Clock (SCLK) for Dynamic PLL ⁵			100	
Input Cycle-to-Cycle Jitter (peak magnitude)			1	ns
CCC Output Peak-to-Peak Period Jitter F_{CCC_OUT}	Max Peak-to-Peak Period Jitter			
	1 Global Network Used	External FB Used	3 Global Networks Used	
0.75 MHz to 24 MHz	0.50%	0.75%	0.70%	
24 MHz to 100 MHz	1.00%	1.50%	1.20%	
100 MHz to 250 MHz	2.50%	3.75%	2.75%	
Acquisition Time				
LockControl = 0			300	μs
LockControl = 1			6.0	ms
Tracking Jitter				
LockControl = 0			2.5	ns
LockControl = 1			1.5	ns
Output Duty Cycle	48.5		51.5	%
Delay Range in Block: Programmable Delay 1 ^{1, 2}	1.25		15.65	ns
Delay Range in Block: Programmable Delay 2 ^{1, 2}	0.025		15.65	ns
Delay Range in Block: Fixed Delay ^{1, 2}		3.5		ns

Notes:

1. This delay is a function of voltage and temperature. See [Table 2-6 on page 2-6](#) and [Table 2-7 on page 2-7](#) for deratings.
2. $T_J = 25^\circ\text{C}$, $V_{CC} = 1.5\text{ V}$
3. The AGLN010, AGLN015, and AGLN020 devices do not support PLL.
4. Tracking jitter is defined as the variation in clock edge position of PLL outputs with reference to the PLL input clock edge. Tracking jitter does not measure the variation in PLL output period, which is covered by the period jitter parameter.
5. Maximum value obtained for a STD speed grade device in Worst-Case Commercial conditions. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) and [Table 2-7 on page 2-7](#) for derating values.

Table 2-93 • IGLOO nano CCC/PLL Specification
 For IGLOO nano V2 Devices, 1.2 V DC Core Supply Voltage

Parameter	Min.	Typ.	Max.	Units
Clock Conditioning Circuitry Input Frequency f_{IN_CCC}	1.5		160	MHz
Clock Conditioning Circuitry Output Frequency f_{OUT_CCC}	0.75		160	MHz
Delay Increments in Programmable Delay Blocks ^{1, 2}		580		ps
Number of Programmable Values in Each Programmable Delay Block			32	
Serial Clock (SCLK) for Dynamic PLL ⁵			60	MHz
Input Cycle-to-Cycle Jitter (peak magnitude)			0.25	ns
CCC Output Peak-to-Peak Period Jitter F_{CCC_OUT}	Max Peak-to-Peak Period Jitter			
	1 Global Network Used	External FB Used	3 Global Networks Used	
0.75 MHz to 24 MHz	0.50%	0.75%	0.70%	
24 MHz to 100 MHz	1.00%	1.50%	1.20%	
100 MHz to 160 MHz	2.50%	3.75%	2.75%	
Acquisition Time				
	LockControl = 0		300	μs
	LockControl = 1		6.0	ms
Tracking Jitter				
	LockControl = 0		4	ns
	LockControl = 1		3	ns
Output Duty Cycle	48.5		51.5	%
Delay Range in Block: Programmable Delay 1 ^{1, 2}	2.3		20.86	ns
Delay Range in Block: Programmable Delay 2 ^{1, 2,}	0.025		20.86	ns
Delay Range in Block: Fixed Delay ^{1, 2}		5.7		ns

Notes:

1. This delay is a function of voltage and temperature. See [Table 2-6 on page 2-6](#) and [Table 2-7 on page 2-7](#) for deratings.
2. $T_J = 25^\circ\text{C}$, $V_{CC} = 1.2\text{ V}$
3. The AGLN010, AGLN015, and AGLN020 devices do not support PLLs.
4. Tracking jitter is defined as the variation in clock edge position of PLL outputs with reference to PLL input clock edge. Tracking jitter does not measure the variation in PLL output period, which is covered by period jitter parameter.
5. Maximum value obtained for a STD speed grade device in Worst-Case Commercial conditions. For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) and [Table 2-7 on page 2-7](#) for derating values.

Note: Peak-to-peak jitter measurements are defined by $T_{\text{peak-to-peak}} = T_{\text{period_max}} - T_{\text{period_min}}$.

Note: For specific junction temperature and voltage supply levels, refer to [Table 2-6 on page 2-6](#) for derating values.

Part Number and Revision Date

Part Number 51700110-002-2
Revised April 2009

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Table 3 •

Previous Version	Changes in Current Version (Advance v0.3)	Page
Advance v0.2 (November 2008)	Reference to the –F speed grade was removed from this document, since it is no longer offered for IGLOO nano devices.	2-1
Advance v0.1 (October 2008)	The table notes and references were revised in Table 2-2 · Recommended Operating Conditions ¹ . VMV was included with V _{CCI} and a table note was added stating, "VMV pins must be connected to the corresponding V _{CCI} pins. See Pin Descriptions for further information." Please review carefully.	2-2
	V _{JTAG} was added to the list in the table note for Table 2-8 · Quiescent Supply Current (I_{DD}) Characteristics, IGLOO nano Flash*Freeze Mode* . Values were added for AGLN010, AGLN015, and AGLN030 for 1.5 V.	2-7
	V _{CCI} was removed from the list in the table note for Table 2-9 · Quiescent Supply Current (I_{DD}) Characteristics, IGLOO nano Sleep Mode (V_{CC} = 0 V)* .	2-7
	Values for I _{CCA} current were updated for AGLN010, AGLN015, and AGLN030 in Table 2-11 · Quiescent Supply Current (I_{DD}), No IGLOO nano Flash*Freeze Mode 1.	2-8
	Values for PAC1 and PAC2 were added to Table 2-14 · Different Components Contributing to Dynamic Power Consumption in IGLOO nano Devices and Table 2-16 · Different Components Contributing to Dynamic Power Consumption in IGLOO nano Devices .	2-10, 2-11
	Table notes regarding wide range support were added to Table 2-20 · Summary of Maximum and Minimum DC Input and Output Levels .	2-19
	1.2 V LVCMOS wide range values were added to Table 2-21 · Summary of Maximum and Minimum DC Input Levels and Table 2-22 · Summary of AC Measuring Points .	2-19, 2-20
	The following table note was added to Table 2-24 · Summary of I/O Timing Characteristics—Software Default Settings and Table 2-25 · Summary of I/O Timing Characteristics—Software Default Settings : "All LVCMOS 3.3 V software macros support LVCMOS 3.3 V wide range, as specified in the JESD8-B specification."	2-21
	3.3 V LVCMOS Wide Range and 1.2 V Wide Range were added to Table 2-27 · I/O Output Buffer Maximum Resistances ¹ and Table 2-29 · I/O Short Currents IOSH/IOSL .	2-22, 2-23

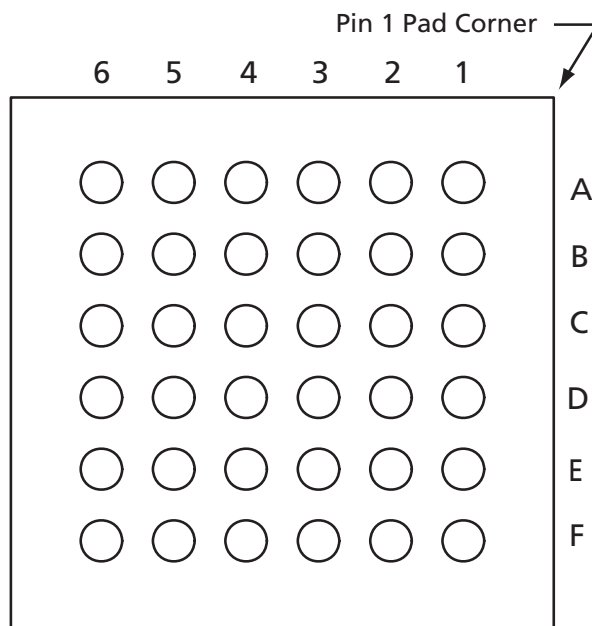

Actel Safety Critical, Life Support, and High-Reliability Applications Policy

The Actel products described in this advance status datasheet may not have completed Actel's qualification process. Actel may amend or enhance products during the product introduction and qualification process, resulting in changes in device functionality or performance. It is the responsibility of each customer to ensure the fitness of any Actel product (but especially a new product) for a particular purpose, including appropriateness for safety-critical, life-support, and other high-reliability applications. Consult Actel's Terms and Conditions for specific liability exclusions relating to life-support applications. A reliability report covering all of Actel's products is available on the Actel website at http://www.actel.com/documents/ORT_Report.pdf. Actel also offers a variety of enhanced qualification and lot acceptance screening procedures. Contact your local Actel sales office for additional reliability information.

Revised March 2009

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (Advance v0.6)	Page
Advance v0.5 (February 2009)	The "100-Pin VQFP" pin table for AGLN030 is new.	3-14
Advance v0.4 (February 2009)	The "100-Pin QFN" section was removed.	N/A
Advance v0.3 (December 2008)	The "81-Pin UC" and "81-Pin CS" pin tables for AGLN020 are new.	3-4, 3-6
	The "81-Pin CS" pin table for AGLN250 is new.	3-7
Advance v0.2 (November 2008)	The "36-Pin UC" pin table is new.	3-2
Advance v0.1 (October 2008)	The "48-Pin QFN" pin diagram was revised.	3-8
	Note 2 for the "48-Pin QFN", "68-Pin QFN", and "100-Pin QFN" pin diagrams was changed to "The die attach paddle of the package is tied to ground (GND)."	3-8, 3-10
	The "100-Pin VQFP" pin diagram was revised to move the pin IDs to the upper left corner instead of the upper right corner.	3-13

Datasheet Categories

Categories

In order to provide the latest information to designers, some datasheets are published before data has been fully characterized. Datasheets are designated as "Product Brief," "Advance," "Preliminary," and "Production." The definitions of these categories are as follows:

Product Brief

The product brief is a summarized version of a datasheet (advance or production) and contains general product information. This document gives an overview of specific device and family information.

Advance

This version contains initial estimated information based on simulation, other products, devices, or speed grades. This information can be used as estimates, but not for production. This label only applies to the DC and Switching Characteristics chapter of the datasheet and will only be used when the data has not been fully characterized.

Preliminary

The datasheet contains information based on simulation and/or initial characterization. The information is believed to be correct, but changes are possible.

Unmarked (production)

This version contains information that is considered to be final.

Export Administration Regulations (EAR)

The products described in this document are subject to the Export Administration Regulations (EAR). They could require an approved export license prior to export from the United States. An export includes release of product or disclosure of technology to a foreign national inside or outside the United States.

Actel Safety Critical, Life Support, and High-Reliability Applications Policy

The Actel products described in this advance status document may not have completed Actel's qualification process. Actel may amend or enhance products during the product introduction and qualification process, resulting in changes in device functionality or performance. It is the responsibility of each customer to ensure the fitness of any Actel product (but especially a new product) for a particular purpose, including appropriateness for safety-critical, life-support, and other high-reliability applications. Consult Actel's Terms and Conditions for specific liability exclusions relating to life-support applications. A reliability report covering all of Actel's products is available on the Actel website at http://www.actel.com/documents/ORT_Report.pdf. Actel also offers a variety of enhanced qualification and lot acceptance screening procedures. Contact your local Actel sales office for additional reliability information.

Section II – Core Architecture

***Low-Power Flash Technology and Flash*Freeze
Mode***

1 – FPGA Array Architecture in Low-Power Flash Devices

Device Architecture

Advanced Flash Switch

Unlike SRAM FPGAs, the low-power flash devices use a live-at-power-up ISP flash switch as their programming element. Flash cells are distributed throughout the device to provide nonvolatile, reconfigurable programming to connect signal lines to the appropriate VersaTile inputs and outputs. In the flash switch, two transistors share the floating gate, which stores the programming information (Figure 1-1). One is the sensing transistor, which is only used for writing and verification of the floating gate voltage. The other is the switching transistor. The latter is used to connect or separate routing nets, or to configure VersaTile logic. It is also used to erase the floating gate. Dedicated high-performance lines are connected as required using the flash switch for fast, low-skew, global signal distribution throughout the device core. Maximum core utilization is possible for virtually any design. The use of the flash switch technology also removes the possibility of firm errors, which are increasingly common in SRAM-based FPGAs.

Figure 1-1 • Flash-Based Switch

FPGA Array Architecture Support

The flash FPGAs listed in [Table 1-1](#) support the architecture features described in this document.

Table 1-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO®	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC®3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 1-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

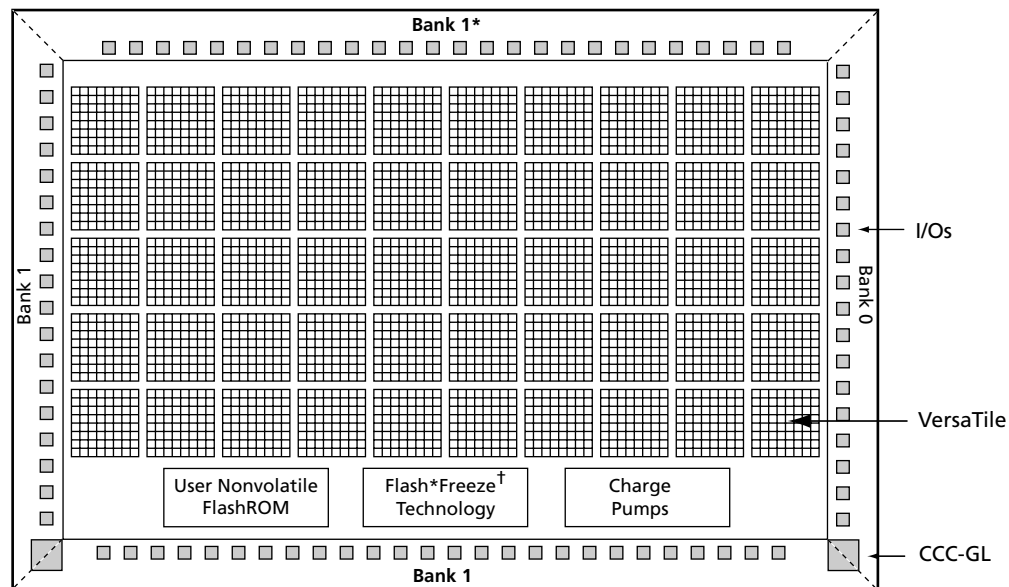

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 1-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Device Overview

The low-power flash devices consist of multiple distinct programmable architectural features (Figure 1-5 on page 1-5 through Figure 1-7 on page 1-6):

- FPGA fabric/core (VersaTiles)
- Routing and clock resources (VersaNets)
- FlashROM
- Dedicated SRAM and/or FIFO
 - 30 k gate and smaller device densities do not support SRAM or FIFO.
 - Automotive devices do not support FIFO operation.
- I/O structures
- Flash*Freeze technology and low-power modes

Notes: * Bank 0 for the 30 k devices

† Flash*Freeze mode is supported on IGLOO devices.

Figure 1-2 • IGLOO and ProASIC3 nano Device Architecture Overview with Two I/O Banks (applies to 10 k and 30 k device densities, excluding IGLOO PLUS devices)

Note: † Flash*Freeze mode is supported on IGLOO devices.

Figure 1-3 • IGLOO Device Architecture Overview with Two I/O Banks with RAM and PLL (60 k and 125 k gate densities)

Note: † Flash*Freeze mode is supported on IGLOO devices.

Figure 1-4 • IGLOO Device Architecture Overview with Three I/O Banks (AGLN015, AGLN020, A3PN015, and A3PN020)

Note: Flash*Freeze technology only applies to IGLOO and ProASIC3L families.

Figure 1-5 • IGLOO, IGLOO nano, ProASIC3 nano, and ProASIC3/L Device Architecture Overview with Four I/O Banks (AGL600 device is shown)

Note: * AGLP030 does not contain a PLL or support AES security.

Figure 1-6 • IGLOO PLUS Device Architecture Overview with Four I/O Banks

*Note: Flash*Freeze technology only applies to IGLOOe devices.*

Figure 1-7 • IGLOOe and ProASIC3E Device Architecture Overview (AGLE600 device is shown)

Core Architecture

VersaTile

The proprietary IGLOO and ProASIC3 device architectures provide granularity comparable to gate arrays. The device core consists of a sea-of-VersaTiles architecture.

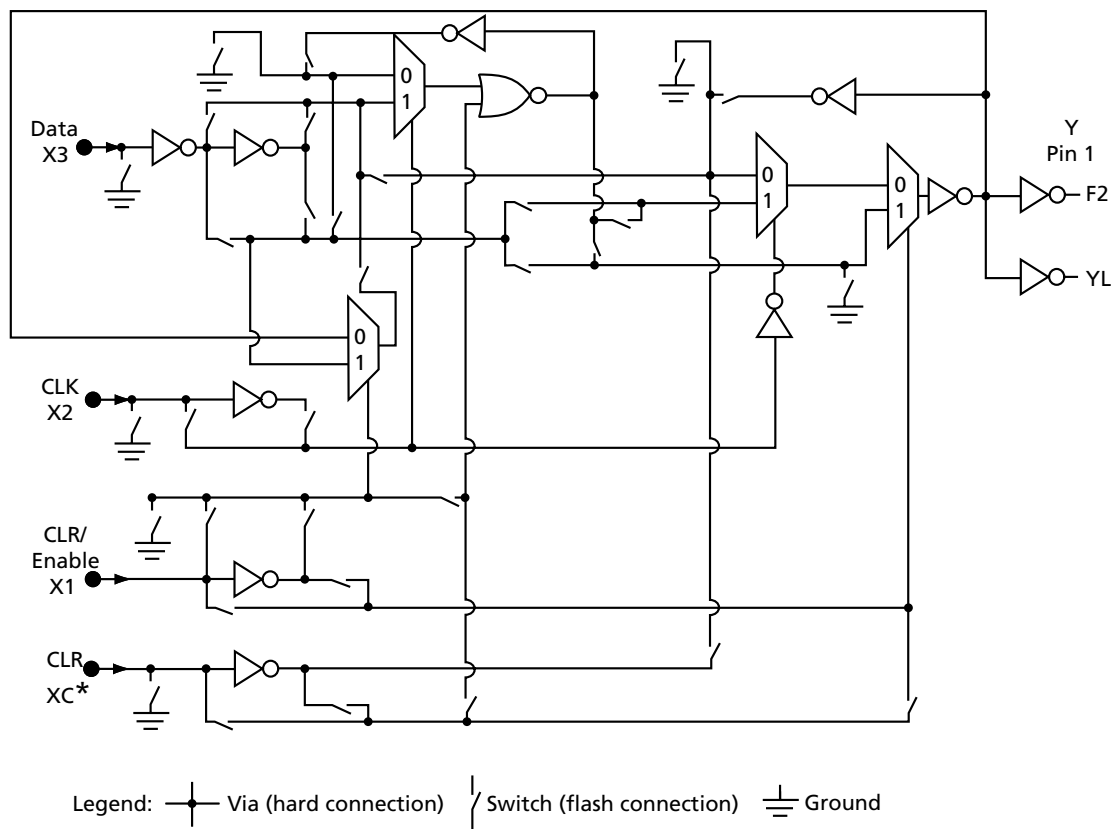

As illustrated in [Figure 1-8](#), there are four inputs in a logic VersaTile cell, and each VersaTile can be configured using the appropriate flash switch connections:

- Any 3-input logic function
- Latch with clear or set
- D-flip-flop with clear or set
- Enable D-flip-flop with clear or set (on a 4th input)

VersaTiles can flexibly map the logic and sequential gates of a design. The inputs of the VersaTile can be inverted (allowing bubble pushing), and the output of the tile can connect to high-speed, very-long-line routing resources. VersaTiles and larger functions can be connected with any of the four levels of routing hierarchy.

When the VersaTile is used as an enable D-flip-flop, SET/CLR is supported by a fourth input. The SET/CLR signal can only be routed to this fourth input over the VersaNet (global) network. However, if, in the user's design, the SET/CLR signal is not routed over the VersaNet network, a compile warning message will be given, and the intended logic function will be implemented by two VersaTiles instead of one.

The output of the VersaTile is F2 when the connection is to the ultra-fast local lines, or YL when the connection is to the efficient long-line or very-long-line resources.

* This input can only be connected to the global clock distribution network.

Figure 1-8 • Low-Power Flash Device Core VersaTile

Array Coordinates

During many place-and-route operations in the Actel Designer software tool, it is possible to set constraints that require array coordinates. Table 1-2 provides array coordinates of core cells and memory blocks for IGLOO and ProASIC3 devices. Table 1-3 provides the information for IGLOO PLUS devices. Table 1-4 on page 1-9 provides the information for IGLOO nano and ProASIC3 nano devices. The array coordinates are measured from the lower left (0, 0). They can be used in region constraints for specific logic groups/blocks, designated by a wildcard, and can contain core cells, memories, and I/Os.

I/O and cell coordinates are used for placement constraints. Two coordinate systems are needed because there is not a one-to-one correspondence between I/O cells and core cells. In addition, the I/O coordinate system changes depending on the die/package combination. It is not listed in Table 1-2. The Designer ChipPlanner tool provides the array coordinates of all I/O locations. I/O and cell coordinates are used for placement constraints. However, I/O placement is easier by package pin assignment.

Figure 1-9 on page 1-9 illustrates the array coordinates of a 600 k gate device. For more information on how to use array coordinates for region/placement constraints, see the *Designer User's Guide* or online help (available in the software) for software tools.

Table 1-2 • IGLOO and ProASIC3 Array Coordinates

Device		VersaTiles				Memory Rows		Entire Die	
		Min.		Max.		Bottom	Top	Min.	Max.
IGLOO	ProASIC3/ ProASIC3L	x	y	x	y	(x, y)	(x, y)	(x, y)	(x, y)

AGLN015	A3PN015	(0, 2)	(32, 9)	None	None	(0, 0)	(34, 9)
AGLN020	A3PN020	(0, 2)	32, 13)	None	None	(0, 0)	(34, 13)
AGLN060	A3PN060	(3, 2)	(66, 25)	None	(3, 26)	(0, 0)	(69, 29)
AGLN125	A3PN125	(3, 2)	(130, 25)	None	(3, 26)	(0, 0)	(133, 29)
AGLN250	A3PN250	(3, 2)	(130, 49)	None	(3, 50)	(0, 0)	(133, 49)

Note: The vertical I/O tile coordinates are not shown. West-side coordinates are $\{(0, 2) \text{ to } (2, 2)\}$ to $\{(0, 77) \text{ to } (2, 77)\}$; east-side coordinates are $\{(195, 2) \text{ to } (197, 2)\}$ to $\{(195, 77) \text{ to } (197, 77)\}$.

Figure 1-9 • Array Coordinates for AGL600, AGL600, A3P600, and A3PE600

Routing Architecture

The routing structure of low-power flash devices is designed to provide high performance through a flexible four-level hierarchy of routing resources: ultra-fast local resources; efficient long-line resources; high-speed, very-long-line resources; and the high-performance VersaNet networks.

The ultra-fast local resources are dedicated lines that allow the output of each VersaTile to connect directly to every input of the eight surrounding VersaTiles (Figure 1-10 on page 1-10). The exception to this is that the SET/CLR input of a VersaTile configured as a D-flip-flop is driven only by the VersaTile global network.

The efficient long-line resources provide routing for longer distances and higher-fanout connections. These resources vary in length (spanning one, two, or four VersaTiles), run both vertically and horizontally, and cover the entire device (Figure 1-11 on page 1-11). Each VersaTile can drive signals onto the efficient long-line resources, which can access every input of every VersaTile. Routing software automatically inserts active buffers to limit loading effects.

The high-speed, very-long-line resources, which span the entire device with minimal delay, are used to route very long or high-fanout nets: length ± 12 VersaTiles in the vertical direction and length ± 16 in the horizontal direction from a given core VersaTile (Figure 1-12 on page 1-11). Very long lines in low-power flash devices have been enhanced over those in previous ProASIC families. This provides a significant performance boost for long-reach signals.

The high-performance VersaNet global networks are low-skew, high-fanout nets that are accessible from external pins or internal logic. These nets are typically used to distribute clocks, resets, and other high-fanout nets requiring minimum skew. The VersaNet networks are implemented as clock trees, and signals can be introduced at any junction. These can be employed hierarchically, with signals accessing every input of every VersaTile. For more details on VersaNets, refer to [Global Resources in Actel Low-Power Flash Devices](#).

Note: Input to the core cell for the D-flip-flop set and reset is only available via the VersaNet global network connection.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet. To improve usability for customers, the device architecture information has now been split into handbook sections, which also include usage information. No technical changes were made to the content unless explicitly listed.

Part Number 51700094-002-4

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 1-1 · Flash-Based FPGAs .	1-2
	Figure 1-2 · IGLOO and ProASIC3 nano Device Architecture Overview with Two I/O Banks (applies to 10 k and 30 k device densities, excluding IGLOO PLUS devices) through Figure 1-5 · IGLOO, IGLOO nano, ProASIC3 nano, and ProASIC3/L Device Architecture Overview with Four I/O Banks (AGL600 device is shown) are new.	1-3, 1-4
	Table 1-4 · IGLOO nano and ProASIC3 nano Array Coordinates is new.	1-9
v1.2 (June 2008)	The title of this document was changed from "Core Architecture of IGLOO and ProASIC3 Devices" to "FPGA Array Architecture in Low-Power Flash Devices."	1-1
	The "FPGA Array Architecture Support" section was revised to include new families and make the information more concise.	1-2
	Table 1-2 · IGLOO and ProASIC3 Array Coordinates was updated to include Military ProASIC3/EL and RT ProASIC3 devices.	1-8
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 1-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> ProASIC3L was updated to include 1.5 V. The number of PLLs for ProASIC3E was changed from five to six. 	1-2
v1.0 (January 2008)	Table 1-1 · Flash-Based FPGAs and the accompanying text was updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "Device Overview" section are new.	1-2
	The "Device Overview" section was updated to note that 15 k devices do not support SRAM or FIFO.	1-3
	Figure 1-6 · IGLOO PLUS Device Architecture Overview with Four I/O Banks is new.	1-5
	Table 1-2 · IGLOO and ProASIC3 Array Coordinates was updated to add A3P015 and AGL015.	1-8
	Table 1-3 · IGLOO PLUS Array Coordinates is new.	1-8

2 – Actel's Flash*Freeze Technology and Low-Power Modes

Flash*Freeze Technology and Low-Power Modes

Actel IGLOO,® IGLOO nano, IGLOO PLUS, ProASIC®3L, and Radiation-Tolerant (RT) ProASIC3 FPGAs with Flash*Freeze technology are designed to meet the most demanding power and area challenges of today's portable electronics products with a reprogrammable, small-footprint, full-featured flash FPGA. These devices offer lower power consumption in static and dynamic modes, utilizing the unique Flash*Freeze technology, than any other FPGA or CPLD.

IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 devices offer various power-saving modes that enable every system to utilize modes that achieve the lowest total system power. Low Power Active capability (static idle) allows for ultra-low power consumption while the device is operational in the system by maintaining SRAM, registers, I/Os, and logic functions.

Flash*Freeze technology provides an ultra-low-power static mode (Flash*Freeze mode) that retains all SRAM and register information with rapid recovery to Active (operating) mode. IGLOO nano and IGLOO PLUS devices have an additional feature when operating in Flash*Freeze mode, allowing them to retain I/O states as well as SRAM and register states. This mechanism enables the user to quickly (within 1 μ s) enter and exit Flash*Freeze mode by activating the Flash*Freeze (FF) pin while all power supplies are kept in their original states. In addition, I/Os and clocks connected to the FPGA can still be toggled without impact on device power consumption. While in Flash*Freeze mode, the device retains all core register states and SRAM information. This mode can be configured so that no power is consumed by the I/O banks, clocks, JTAG pins, or PLLs; and the IGLOO and IGLOO PLUS devices consume as little as 5 μ W, while IGLOO nano devices consume as little as 2 μ W. Actel offers a state management IP core to aid users in gating clocks and managing data before entering Flash*Freeze mode.

This document will guide users in selecting the best low-power mode for their applications, and introduces Actel's Flash*Freeze management IP core.

Actel's Flash Families Support the Flash*Freeze Feature

The low-power flash FPGAs listed in [Table 2-1](#) support the Flash*Freeze feature and the functions described in this document.

Table 2-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 2-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 2-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Low-Power Modes Overview

Table 2-2 summarizes the low-power modes that achieve power consumption reduction when the FPGA or system is idle.

Table 2-2 • Power Modes Summary

Mode		V _{CCI}	V _{CC}	Core	Clocks	ULSICC Macro	To Enter Mode	To Resume Operation	Trigger
Active		On	On	On	On	N/A	Initiate clock	None	–
Static	Idle	On	On	On	Off	N/A	Stop clock	Initiate clock	External
	Flash*Freeze type 1	On	On	On	On*	N/A	Assert FF pin	Deassert FF pin	External
	Flash*Freeze type 2	On	On	On	On*	Used to enter Flash*Freeze mode	Assert FF pin and assert LSICC	Deassert FF pin	External
Sleep		On	Off	Off	Off	N/A	Shut down V _{CC}	Turn on V _{CC} supply	External
Shutdown		Off	Off	Off	Off	N/A	Shut down V _{CC} and V _{CCI} supplies	Turn on V _{CC} and V _{CCI} supplies	External

* External clocks can be left toggling while the device is in Flash*Freeze mode. Clocks generated by the embedded PLL will be turned off automatically.

Static (Idle) Mode

In Static (Idle) mode, none of the clock inputs is switching, and static power is the only power consumed by the device. This mode can be achieved by switching off the incoming clocks to the FPGA, thus benefitting from reduced power consumption. In addition, I/Os draw only minimal leakage current. In this mode, embedded SRAM, I/Os, and registers retain their values so the device can enter and exit this mode just by switching the clocks on or off.

If the device-embedded PLL is used as the clock source, Static (Idle) mode can easily be entered by pulling the PLL POWERDOWN pin LOW (active Low), which will turn off the PLL.

Flash*Freeze Mode

IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 FPGAs offer an ultra-low static power mode to reduce power consumption while preserving the state of the registers, SRAM contents, and I/O states (IGLOO nano and IGLOO PLUS only) without switching off any power supplies, inputs, or input clocks.

Flash*Freeze technology enables the user to switch to Flash*Freeze mode within 1 μ s, thus simplifying low-power design implementation. The Flash*Freeze (FF) pin (active Low) is a dedicated pin used to enter or exit Flash*Freeze mode directly; or the pin can be routed internally to the FPGA core and state management IP to allow the user's application to decide if and when it is safe to transition to this mode. If the FF pin is not used, it can be used as a regular I/O.

The FF pin has a built-in glitch filter and optional Schmitt trigger (not available for all devices) to prevent entering or exiting Flash*Freeze mode accidentally.

There are two ways to use Flash*Freeze mode. In Flash*Freeze type 1, entering and exiting the mode is exclusively controlled by the assertion and deassertion of the FF pin. This enables an external processor or human interface device to directly control Flash*Freeze mode; however, valid data must be preserved using standard procedures (refer to the "[Flash*Freeze Mode Device Behavior](#)" section on page 2-9). In Flash*Freeze mode type 2, entering and exiting the mode is controlled by both the FF pin AND user-defined logic. Flash*Freeze management IP may be used in type 2 mode for clock and data management while entering and exiting Flash*Freeze mode.

Flash*Freeze Type 1: Control by Dedicated Flash*Freeze Pin

Flash*Freeze type 1 is intended for systems where either the device will be reset upon exiting Flash*Freeze mode, or data and clock are managed externally. The device enters Flash*Freeze mode 1 μ s after the dedicated FF pin is asserted (active Low), and returns to normal operation when the FF pin is deasserted (High) ([Figure 2-1 on page 2-5](#)). In this mode, FF pin assertion or deassertion is the only condition that determines entering or exiting Flash*Freeze mode.

In Actel Libero® Integrated Design Environment (IDE) v8.2 and before, this mode is implemented by enabling Flash*Freeze mode (default setting) in the Compile options of the Actel Designer software. To simplify usage of Flash*Freeze mode, beginning with Libero IDE v8.3, an INBUF_FF I/O macro was introduced. An INBUF_FF I/O buffer must be used to identify the Flash*Freeze input. Actel recommends switching to the new implementation.

In Libero IDE v8.3 and later, the user must manually instantiate the INBUF_FF macro in the top level of the design to implement Flash*Freeze Type 1, as shown in [Figure 2-1 on page 2-5](#).

Figure 2-1 shows the concept of FF pin control in Flash*Freeze mode type 1.

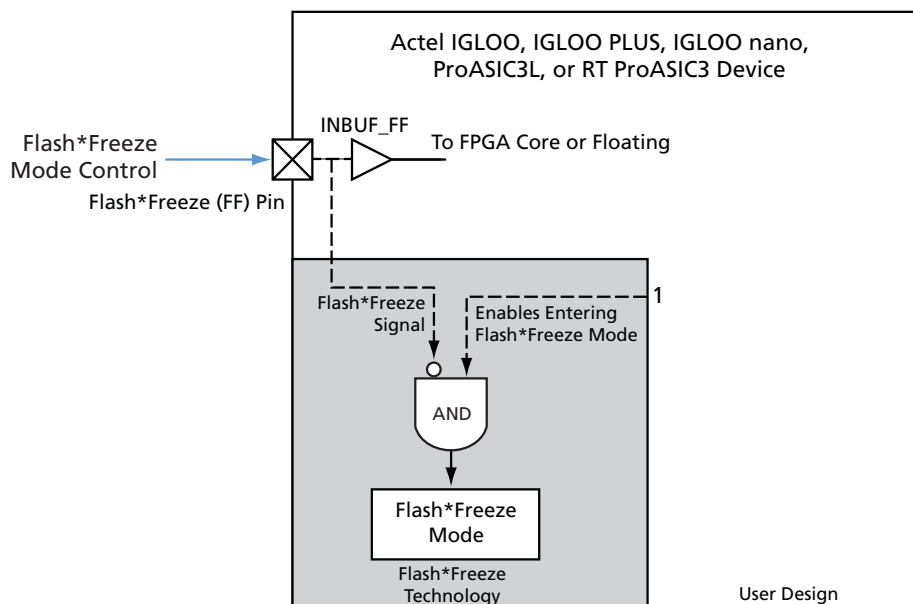

Figure 2-1 • Flash*Freeze Mode Type 1 – Controlled by the Flash*Freeze Pin

Figure 2-2 shows the timing diagram for entering and exiting Flash*Freeze mode type 1.

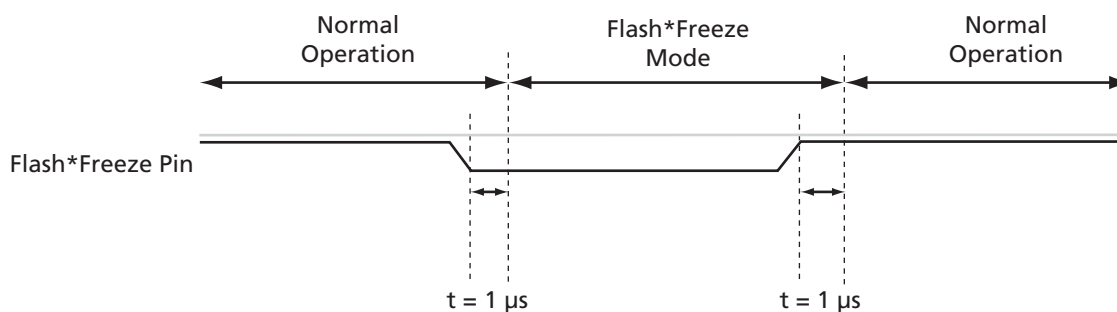

Figure 2-2 • Flash*Freeze Mode Type 1 – Timing Diagram

Flash*Freeze Type 2: Control by Dedicated Flash*Freeze Pin and Internal Logic

The device can be made to enter Flash*Freeze mode by activating the FF pin together with Actel's Flash*Freeze management IP core (refer to the "Flash*Freeze Management IP" section on page 2-15 for more information) or user-defined control logic (Figure 2-3) within the FPGA core. This method enables the design to perform important activities before allowing the device to enter Flash*Freeze mode, such as transitioning into a safe state, completing the processing of a critical event. Designers are encouraged to take advantage of Actel's Flash*Freeze Management IP to handle clean entry and exit of Flash*Freeze mode (described later in this document). The device will only enter Flash*Freeze mode when the Flash*Freeze pin is asserted (active Low) and the User Low Static I_{CC} (ULSICC) macro input signal, called the LSICC signal, is asserted (High). One condition is not sufficient to enter Flash*Freeze mode type 2; both the FF pin and LSICC signal must be asserted.

When Flash*Freeze type 2 is implemented in the design, the ULSICC macro needs to be instantiated by the user. There are no functional differences in the device whether the ULSICC macro is instantiated or not, and whether the LSICC signal is asserted or deasserted. The LSICC signal is used only to control entering Flash*Freeze mode. Figure 2-4 on page 2-7 shows the timing diagram for entering and exiting Flash*Freeze mode type 2.

After exiting Flash*Freeze mode type 2 by deasserting the Flash*Freeze pin, the LSICC signal must be deasserted by the user design. This will prevent entering Flash*Freeze mode by asserting the Flash*Freeze pin only.

Refer to Table 2-3 for Flash*Freeze (FF) pin and LSICC signal assertion and deassertion values.

Table 2-3 • Flash*Freeze Mode Type 1 and Type 2 – Signal Assertion and Deassertion Values

Signal	Assertion Value	Deassertion Value
Flash*Freeze (FF) pin	Low	High
LSICC signal	High	Low

Notes:

1. The Flash*Freeze (FF) pin is an active-Low signal, and LSICC is an active-High signal.
2. The LSICC signal is used only in Flash*Freeze mode type 2.

Figure 2-3 • Flash*Freeze Mode Type 2 – Controlled by Flash*Freeze Pin and Internal Logic (LSICC signal)

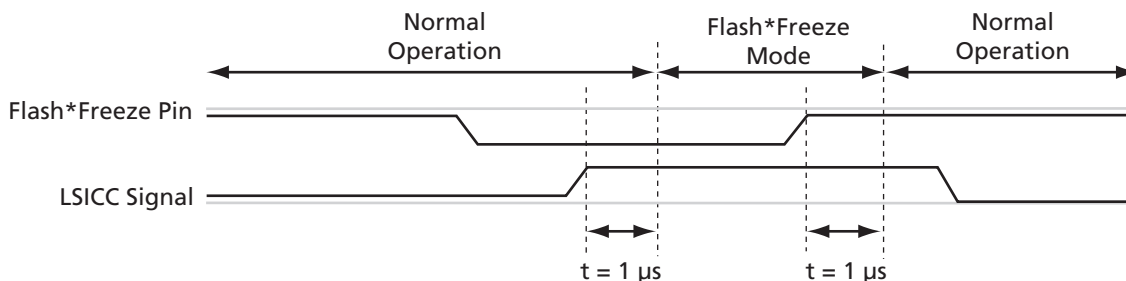

Figure 2-4 • Flash*Freeze Mode Type 2 – Timing Diagram

Table 2-4 summarizes the Flash*Freeze mode implementations.

Table 2-4 • Flash*Freeze Mode Usage

Flash*Freeze Mode Type	Description	Flash*Freeze Pin State	Instantiate ULSICC Macro	LSICC Signal	Operating Mode
1	Flash*Freeze mode is controlled only by the FF pin.	Deasserted	No	N/A	Normal operation
		Asserted	No	N/A	Flash*Freeze mode
2	Flash*Freeze mode is controlled by the FF pin and LSICC signal.	"Don't care"	Yes	Deasserted	Normal operation
		Deasserted	Yes	"Don't care"	Normal operation
		Asserted	Yes	Asserted	Flash*Freeze mode

Note: Refer to Table 2-3 on page 2-6 for Flash*Freeze pin and LSICC signal assertion and deassertion values.

IGLOO, ProASIC3L, and RT ProASIC3 I/O State in Flash*Freeze Mode

In IGLOO and ProASIC3L devices, when the device enters Flash*Freeze mode, I/Os become tristated. If the weak pull-up or pull-down feature is used, the I/Os will maintain the configured weak pull-up or pull-down status. This feature enables the design to set the I/O state to a certain level that is determined by the pull-up/-down configuration.

Table 2-5 shows the I/O pad state based on the configuration and buffer type.

Note that configuring weak pull-up or pull-down for the FF pin is not allowed. The FF pin can be configured as a Schmitt trigger input in IGLOOe, IGLOO nano, IGLOO PLUS, and ProASIC3EL devices.

Table 2-5 • IGLOO, ProASIC3L, and RT ProASIC3 Flash*Freeze Mode (type 1 and type 2)—I/O Pad State

Buffer Type		I/O Pad Weak Pull-Up/-Down	I/O Pad State in Flash*Freeze Mode
Input/Global		Enabled	Weak pull-up/pull-down*
		Disabled	Tristate*
Output		Enabled	Weak pull-up/pull-down
		Disabled	Tristate
Bidirectional / Tristate Buffer	E = 0 (input/tristate)	Enabled	Weak pull-up/pull-down*
		Disabled	Tristate*
	E = 1 (output)	Enabled	Weak pull-up/pull-down
		Disabled	Tristate

* Internal core logic driven by this input/global buffer will be tied High as long as the device is in Flash*Freeze mode.

IGLOO nano and IGLOO PLUS I/O State in Flash*Freeze Mode

In IGLOO nano and IGLOO PLUS devices, users have multiple options in how to configure I/Os during Flash*Freeze mode:

1. Hold the previous state
2. Set I/O pad to weak pull-up or pull-down
3. Tristate I/O pads

The I/O configuration must be configured by the user in the I/O Attribute Editor or in a PDC constraint file, and can be done on a pin-by-pin basis. The output hold feature will hold the output in the last registered state, using the I/O pad weak pull-up or pull-down resistor when the FF pin is asserted. When inputs are configured with the hold feature enabled, the FPGA core side of the input will hold the last valid state of the input pad before the device entered Flash*Freeze mode. The input pad can be driven to any value, configured as tristate, or configured with the weak pull-up or pull-down I/O pad feature during Flash*Freeze mode without affecting the hold state. If the weak pull-up or pull-down feature is used without the output hold feature, the input and output pads will maintain the configured weak pull-up or pull-down status during Flash*Freeze mode and normal operation. If a fixed weak pull-up or pull-down is defined on an output buffer or as bidirectional in output mode, and a hold state is also defined for the same pin, the pin will be configured in hold state mode during Flash*Freeze mode. During normal operation, the pin will be configured with the predefined weak pull-up or pull-down. Any I/Os that do not use the hold state or I/O pad weak pull-up or pull-down features will be tristated during Flash*Freeze mode and the FPGA core will be driven High by inputs. Inputs that are tristated during Flash*Freeze mode may be left floating without any reliability concern or impact to power consumption.

Table 2-6 shows the I/O pad state based on the configuration and buffer type.

Note that configuring weak pull-up or pull-down for the FF pin is not allowed.

Table 2-6 • IGLOO nano and IGLOO PLUS Flash*Freeze Mode (type 1 and type 2)—I/O Pad State

Buffer Type		Hold State	I/O Pad Weak Pull-Up/-Down	I/O Pad State in Flash*Freeze Mode
Input		Enabled	Enabled	Weak pull-up/pull-down ¹
		Disabled	Enabled	Weak pull-up/pull-down ²
		Enabled	Disabled	Tristate ¹
		Disabled	Disabled	Tristate ²
Output		Enabled	"Don't care"	Weak pull to hold state
		Disabled	Enabled	Weak pull-up/pull-down
		Disabled	Disabled	Tristate
Bidirectional / Tristate Buffer	E = 0 (input/tristate)	Enabled	Enabled	Weak pull-up/pull-down ¹
		Disabled	Enabled	Weak pull-up/pull-down ²
		Enabled	Disabled	Tristate ¹
		Disabled	Disabled	Tristate ²
	E = 1 (output)	Enabled	"Don't care"	Weak pull to hold state ³
		Disabled	Enabled	Weak pull-up/pull-down
		Disabled	Disabled	Tristate

Notes:

1. Internal core logic driven by this input buffer will be set to the value this I/O had when entering Flash*Freeze mode.
2. Internal core logic driven by this input buffer will be tied High as long as the device is in Flash*Freeze mode.
3. For bidirectional buffers: Internal core logic driven by the input portion of the bidirectional buffer will be set to the hold state.

Flash*Freeze Mode Device Behavior

Entering Flash*Freeze Mode

- Actel IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 devices are designed and optimized to enter Flash*Freeze mode only when power supplies are stable. If the device is being powered up while the FF pin is asserted (Flash*Freeze mode type 1), or while both FF pin and LSICC signal are asserted (Flash*Freeze mode type 2), the device is expected to enter Flash*Freeze mode within 5 μ s after the I/Os and FPGA core have reached their activation levels.
- If the device is already powered up when the FF pin is asserted, the device will enter Flash*Freeze mode within 1 μ s (type 1). In Flash*Freeze mode type 2 operation, entering Flash*Freeze mode is completed within 1 μ s after both FF pin and LSICC signal are asserted. Exiting Flash*Freeze mode is completed within 1 μ s after deasserting the FF pin only.

PLLs

- If an embedded PLL is used, entering Flash*Freeze mode will automatically power down the PLL.
- The PLL output clocks will stop toggling within 1 μ s after the assertion of the FF pin in type 1, or after both FF pin and LSICC signal are asserted in type 2. At the same time, I/Os will transition into the state specified in [Table 2-6 on page 2-8](#). The user design must ensure it is safe to enter Flash*Freeze mode.

I/Os and Globals

- While entering Flash*Freeze mode, inputs, globals, and PLLs will enter their Flash*Freeze state asynchronously to each other. As a result, clock and data glitches and narrow pulses may be generated while entering Flash*Freeze mode, as shown in [Figure 2-5](#).

Figure 2-5 • Narrow Clock Pulses During Flash*Freeze Entrance and Exit

- I/O banks are not all deactivated simultaneously when entering Flash*Freeze mode. This can cause clocks and inputs to become disabled at different times, resulting in unexpected data being captured.
- Upon entering Flash*Freeze mode, all inputs and globals become tied High internally (except when an input hold state is used on IGLOO nano or IGLOO PLUS devices). If any of these signals are driven Low or tied Low externally, they will experience a Low to High transition internally when entering Flash*Freeze mode.
- Upon entering type 2 Flash*Freeze mode, ensure the LSICC signal (active High) does not deassert. This can prevent the device from entering Flash*Freeze mode.
- Asynchronous input to output paths may experience output glitches. For example, on a direct in-to-out path, if the current state is '0' and the input bank turns off first, the input and then the output will transition to '1' before the output enters its Flash*Freeze state. This can be prevented by using latches in asynchronous in-to-out paths.
- The above situations can cause glitches or invalid data to be clocked into and preserved in the device. Refer to the "[Flash*Freeze Design Guide](#)" section on [page 2-13](#) for solutions.

During Flash*Freeze Mode

- PLLs are turned off during Flash*Freeze mode.
- I/O pads are configured according to [Table 2-5 on page 2-7](#) and [Table 2-6 on page 2-8](#).
- Inputs and input clocks to the FPGA can toggle without any impact on static power consumption, assuming weak pull-up or pull-down is not selected.
- If weak pull-up or pull-down is selected and the input is driven to the opposite direction, power dissipation will occur.
- Any toggling signals will be charging and discharging the package pin capacitance.
- IGLOO and ProASIC3L outputs will be tristated unless the I/O is configured with weak pull-up or pull-down. The output of the I/O to the FPGA core is logic High regardless of whether the I/O pin is configured with a weak pull-up or pull-down. Refer to [Table 2-5 on page 2-7](#) for more information.
- IGLOO nano and IGLOO PLUS output behavior will be based on the configuration defined by the user. Refer to [Table 2-6 on page 2-8](#) for a description of output behavior during Flash*Freeze mode.
- The JTAG circuit is active; however, JTAG operations, such as JTAG commands, JTAG bypass, programming, and authentication, cannot be executed. The device must exit Flash*Freeze mode before JTAG commands can be sent. TCK should be static to avoid extra power consumption from the JTAG state machine.
- The FF pin must be externally asserted for the device to stay in Flash*Freeze mode.
- The FF pin is still active; i.e., the pin is used to exit Flash*Freeze mode when deasserted.

Exiting Flash*Freeze Mode

I/Os and Globals

- While exiting Flash*Freeze mode, inputs and globals will exit their Flash*Freeze state asynchronously to each other. As a result, clock and data glitches and narrow pulses may be generated while exiting Flash*Freeze mode, unless clock gating schemes are used.
- I/O banks are not all activated simultaneously when exiting Flash*Freeze mode. This can cause clocks and inputs to become enabled at different times, resulting in unexpected data being captured.
- Upon exiting Flash*Freeze mode, inputs and globals will no longer be tied High internally (does not apply to input hold state on IGLOO nano and IGLOO PLUS). If any of these signals are driven Low or tied Low externally, they will experience a High-to-Low transition internally when exiting Flash*Freeze mode.
- Applies only to IGLOO nano and IGLOO PLUS: Output hold state is asynchronously controlled by the signal driving the output buffer (output signal). This ensures a clean, glitch-free transition from hold state to output drive. However, any glitches on the output signal during exit from Flash*Freeze mode may result in glitches on the output pad.
- The above situations can cause glitches or invalid data to be clocked into and preserved in the device. Refer to the "[Flash*Freeze Design Guide](#)" on [page 2-13](#) for solutions.

PLLs

- If the embedded PLL is used, the design must allow maximum acquisition time (per device datasheet) for the PLL to acquire the lock signal.

Flash*Freeze Pin Locations

Refer to the [Pin Descriptions](#) chapter of the handbook for information regarding Flash*Freeze pin location on the available packages. The Flash*Freeze pin location is independent of the device, allowing migration to larger or smaller devices while maintaining the same pin location on the board.

Sleep and Shutdown Modes

Sleep Mode

Actel IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 FPGAs support Sleep mode when device functionality is not required. In Sleep mode, the FPGA core voltage supply (V_{CC}) is turned off (either grounded or floated) while other power supplies are left on, resulting in the FPGA core being turned off to reduce power consumption. While the device is in Sleep mode, the rest of the system can still be operating and driving the input buffers of the device. The driven inputs do not pull up the internal power planes, and the current draw is limited to minimal leakage current.

Table 2-7 shows the power supply status in Sleep mode. When the V_{CC} power supply is powered off, the corresponding power pin can be left floating or grounded.

Table 2-7 • Sleep Mode—Power Supply Requirement for IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 Devices

Power Supplies	Power Supply State
V_{CC}	Powered off
$V_{CCI} = VMV$	Powered on
V_{JTAG}	Powered on
V_{PUMP}	Powered on

Refer to the "Power-Up/-Down Behavior" section on page 2-12 for more information about I/O states during Sleep mode and the timing diagram for entering and exiting Sleep mode.

Shutdown Mode

Shutdown mode is supported for all IGLOO nano and IGLOO PLUS devices as well the following IGLOO/e devices: AGL015, AGL030, AGL0600, AGL03000, and A3PE3000L. Shutdown mode can be used by turning off all power supplies when the device function is not needed. Cold-sparing and hot-insertion features enable these devices to be powered down without turning off the entire system. When power returns, the live-at-power-up feature enables operation of the device after reaching the voltage activation point.

Using Sleep and Shutdown Modes in the System

Depending on the power supply and the components used in an application, there are many ways to power on or off the power supplies connected to the device. For example, [Figure 2-6](#) shows how a microprocessor can be used to control a power FET. Actel recommends that power FETs with low resistance be used to perform the switching action.

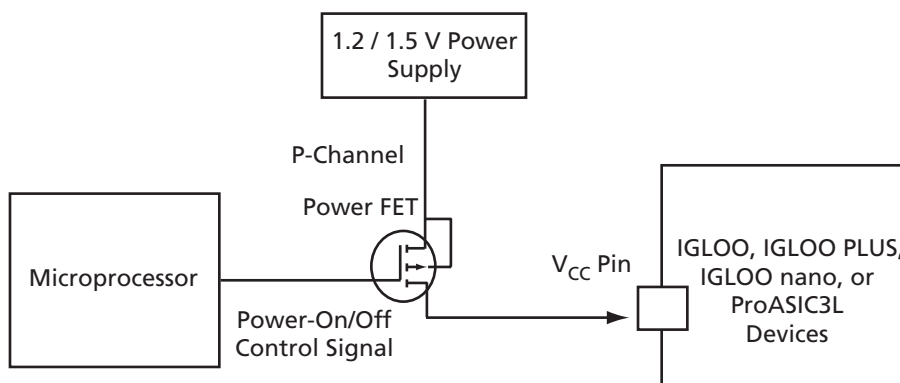

Figure 2-6 • Controlling Power-On/-Off State Using Microprocessor and Power FET

[Figure 2-7](#) shows how a microprocessor can be used with a voltage regulator's shutdown pin to turn on or off the power supplies connected to the device.

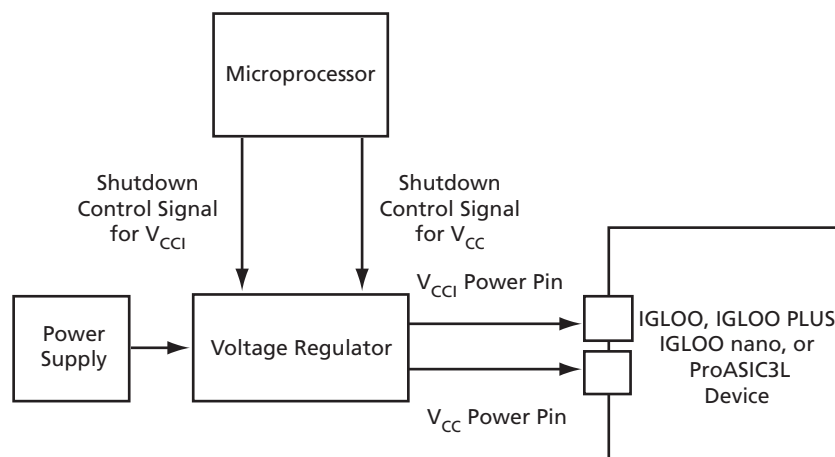

Figure 2-7 • Controlling Power-On/-Off State Using Microprocessor and Voltage Regulator

Power-Up/-Down Behavior

By design, all IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 I/Os are in tristate mode before device power-up. The I/Os remain tristated until the last voltage supply (V_{CC} or V_{CC1}) is powered to its activation level. After the last supply reaches its functional level, the outputs exit the tristate mode and drive the logic at the input of the output buffer. The behavior of user I/Os is independent of the V_{CC} and V_{CC1} sequence or the state of other voltage supplies of the FPGA (V_{PUMP} and V_{JTAG}). During power-down, device I/Os become tristated once the first power supply (V_{CC} or V_{CC1}) drops below its deactivation voltage level. The I/O behavior during power-down is also independent of voltage supply sequencing.

[Figure 2-8 on page 2-13](#) shows a timing diagram when the V_{CC} power supply crosses the activation and deactivation trip points in a typical application when the V_{CC} power supply ramp-rate is 100 μ s (ramping from 0 V to 1.5 V in this example). This is the timing diagram for the FPGA entering and

exiting Sleep mode, as this function is dependent on powering V_{CC} down or up. Depending on the ramp-rate of the power supply and board-level configurations, the user can easily calculate how long it will take for the core to become inactive or active. For more information, refer to [Power-Up/Down Behavior of Low-Power Flash Devices](#).

Figure 2-8 • Entering and Exiting Sleep Mode, Typical Timing Diagram

Context Save and Restore in Sleep or Shutdown Mode

In Sleep mode or Shutdown mode, the contents of the SRAM, state of the I/Os, and state of the registers are lost when the device is powered off, if no other measure is taken. A low-cost external serial EEPROM can be used to save and restore the contents of the device when entering and exiting Sleep mode or Shutdown mode. In the [Embedded SRAM Initialization Using External Serial EEPROM](#) application note, detailed information and a reference design are provided for initializing the embedded SRAM using an external serial EEPROM. The user can easily customize the reference design to save and restore the FPGA state when entering and exiting Sleep mode or Shutdown mode. The microcontroller will need to manage this activity; hence, before powering down V_{CC} , the data will be read from the FPGA and stored externally. In a similar way, after the FPGA is powered up, the microcontroller will allow the FPGA to load the data from external memory and restore its original state.

Flash*Freeze Design Guide

This section describes how designers can create reliable designs that use ultra-low-power Flash*Freeze modes optimally. The section below provides guidance on how to select the best Flash*Freeze mode for any application. The "Design Solutions" section on page 2-14 gives specific recommendations on how to design and configure clocks, set/reset signals, and I/Os. This section also gives an overview of the design flow and provides details concerning Actel's Flash*Freeze Management IP, which enables clean clock gating and housekeeping. The "Additional Power Conservation Techniques" section on page 2-20 describes board-level considerations for entering and exiting Flash*Freeze mode.

Selecting the Right Flash*Freeze Mode

Both Flash*Freeze modes will bring an FPGA into an ultra-low-power static mode that retains register and SRAM content and sets I/Os to a predetermined configuration. There are two primary differences that distinguish type 2 mode from type 1, and they must be considered when creating a design using Flash*Freeze technology.

First, with type 2 mode, the device has an opportunity to wait for a second signal to enable activation of Flash*Freeze mode. This allows processes to complete prior to deactivating the device, and can be useful to control task completion, data preservation, accidental Flash*Freeze activation, system shutdown, or any other housekeeping function. The second signal may be derived from an external or in-to-out internal source. The second difference between type 1 and type 2 modes is that a design for type 2 mode has an opportunity to cleanly manage clocks and data activity before entering and exiting Flash*Freeze mode. This is particularly important when data preservation is needed, as it ensures valid data is stored prior to entering, and upon exiting, Flash*Freeze mode.

Type 1 Flash*Freeze mode is ideally suited for applications with the following design criteria:

- Entering Flash*Freeze mode is not dependent on any signal other than the external FF pin.
- Internal housekeeping is not required prior to entering Flash*Freeze.
- The device is reset upon exiting Flash*Freeze mode or internal state saving is not required.
- State saving is required, but data and clock management is performed external to the FPGA. In other words, incoming data is externally guaranteed and held valid prior to entering Flash*Freeze mode.

Type 2 Flash*Freeze mode is ideally suited for applications with the following design criteria:

- Entering Flash*Freeze mode is dependent on an internal or external signal in addition to the external FF pin.
- State saving is required and incoming data is not externally guaranteed valid.
- The designer wants to use his/her own Flash*Freeze management IP for clock and data management.
- The designer wants to use his/her own Flash*Freeze management logic for clock and data management.
- Internal housekeeping is required prior to entering Flash*Freeze mode. Housekeeping activities may include loading data to SRAM, system shutdown, completion of current task, or ensuring valid Flash*Freeze pin assertion.

There is no downside to type 2 mode, and Actel's Flash*Freeze management IP offers a very low tile count clock and data management solution. Actel's recommendation for most designs is to use type 2 Flash*Freeze mode with Flash*Freeze management IP.

Design Solutions

Clocks

- Actel recommends using a completely synchronous design in Type 2 mode with Flash*Freeze management IP cleanly gating all internal and external clocks. This will prevent narrow pulses upon entrance and exit from Flash*Freeze mode ([Figure 2-5 on page 2-9](#)).
- Upon entering Flash*Freeze mode, external clocks become tied off High, internal to the clock pin (unless hold state is used on IGLOO nano or IGLOO PLUS), and PLLs are turned off. Any clock that is externally Low will realize a Low to High transition internal to the device while entering Flash*Freeze. If clocks will float during Flash*Freeze mode, Actel recommends using the weak pull-up feature. If clocks will continue to drive the device during Flash*Freeze mode, the clock gating (filter) available in Flash*Freeze management IP can help to filter unwanted narrow clock pulses upon Flash*Freeze mode entry and exit.
- Clocks may continue to drive FPGA pins while the device is in Flash*Freeze mode, with virtually no power consumption. The weak pull-up/-down configuration will result in unnecessary power consumption if used in this scenario.
- Floating clocks can cause totem pole currents on the input I/O circuitry when the device is in active mode. If clocks are externally gated prior to entering Flash*Freeze mode, Actel recommends gating them to a known value (preferably '1', to avoid a possible narrow pulse upon Flash*Freeze mode exit), and not leaving them floating. However, during Flash*Freeze mode, all inputs and clocks are internally tied off to prevent totem pole currents, so they can be left floating.
- Upon exiting Flash*Freeze mode, the design must allow maximum acquisition time for the PLL to acquire the lock signal, and for a PLL clock to become active. If a PLL output clock is used as the primary clock for Flash*Freeze management IP, it is important to note that the clock gating circuit will only release other clocks after the primary PLL output clock becomes available.

Set/Reset

Since all I/Os and globals are tied High in Flash*Freeze mode (unless hold state is used on IGLOO nano or IGLOO PLUS), Actel recommends using active low set/reset at the top-level port. If needed, the signal can be inverted internally.

- If the intention is to always set/reset in Flash*Freeze mode, a self set/reset circuit may be implemented to accomplish this, as shown in Figure 2-9. Configure an active High set/reset input pin so it uses the internal pull-up during Flash*Freeze mode, and drives Low during active mode. When the device exits Flash*Freeze mode, the input will transition from High to Low, releasing the set/reset. Note that this circuit may release set/reset before all outputs become active, since outputs are enabled up to 200 ns after inputs when exiting Flash*Freeze mode.

Figure 2-9 • Flash*Freeze Self-Reset Circuit

I/Os

- Floating inputs can cause totem pole currents on the input I/O circuitry when the device is in active mode. If inputs will be released (undriven) during Flash*Freeze mode, Actel recommends that they are only released after the device enters Flash*Freeze mode.
- As mentioned earlier, asynchronous input to output paths are subject to possible glitching when entering Flash*Freeze mode. For example, on a direct in-to-out path, if the current state is '0' and the input bank deactivates first, the input and then the output will transition to '1' before the output enters its Flash*Freeze state. This can be prevented by using latches along with Flash*Freeze management IP to gate asynchronous in-to-out paths prior to entering Flash*Freeze mode.

JTAG

- The JTAG state machine is powered but not active during Flash*Freeze mode.
- TCK should be held in a static state to prevent dynamic power consumption of the JTAG circuit during Flash*Freeze.
- Specific JTAG pin tie-off recommendations suitable for Flash*Freeze mode can be found in the [Pin Descriptions](#) chapter of the handbook.

ULSICC

- The User Low Static ICC (ULSICC) macro acts as an access point to the hard Flash*Freeze technology block in the device. The ULSICC macro represents a hard, fixed location block in the device. When the LSICC input of the ULSICC macro is driven Low, the Flash*Freeze pin is blocked, and when LSICC is driven High, the Flash*Freeze pin is enabled.
- If the user decides to build his/her own Flash*Freeze type 2 clock and data management logic, note that the LSICC signal on the ULSICC macro is ANDed internally with the Flash*Freeze signal. In order to reliably enter Flash*Freeze, the LSICC signal must remain asserted High while entering and during Flash*Freeze mode.

Flash*Freeze Management IP

One of the key benefits of Actel's Flash*Freeze mode is the ability to preserve the state of all internal registers, SRAM content, and I/Os (IGLOO nano and IGLOO PLUS only). This feature enables seamless continuation of data processing before and after Flash*Freeze, without the need to reload or reinitialize the FPGA system. Actel's Flash*Freeze management IP, available for type 2 implementation, offers a robust RTL block that ensures clean clock gating of all system clocks before entering and upon exiting Flash*Freeze mode. This IP also gives users the option to perform housekeeping prior to entering Flash*Freeze mode. This section will provide an overview of the Flash*Freeze management IP. Additional information on this IP core can be found in the Libero IDE online help.

The Flash*Freeze management IP is comprised of three blocks: the Flash*Freeze finite state machine (FSM), the clock gating (filter) block, and the ULSICC macro, as shown in Figure 2-10.

Figure 2-10 • Flash*Freeze Management IP Block Diagram

Flash*Freeze Management FSM

The Flash*Freeze FSM block is a simple, robust, fully encoded 3-bit state machine that ensures clean entrance to and exit from Flash*Freeze mode by controlling activities of the clock gating, ULSICC, and optional housekeeping blocks. The state diagram for the FSM is shown in Figure 2-12 on page 2-18, below. In normal operation, the state machine waits for Flash*Freeze pin assertion, and upon detection of a request, it waits for a short period of time to ensure the assertion persists; then it asserts **WAIT_HOUSEKEEPING** (active High) synchronous to the user's designated system clock. This flag can be used by user logic to perform any needed shutdown processes prior to entering Flash*Freeze mode, such as storing data into SRAM, notifying other system components of the request, or timing/validating the Flash*Freeze request. The FSM also asserts **Flash_Freeze_Enabled** whenever the device enters Flash*Freeze mode. This occurs after all housekeeping and clock gating functions have completed. The **Flash_Freeze_Enabled** signal remains asserted, even during Flash*Freeze mode, until the Flash*Freeze pin is deasserted. Use the **Flash_Freeze_Enabled** signal to drive any logic in the design that needs to be in a particular state during Flash*Freeze mode. The **DONE_HOUSEKEEPING** (active High) signal should be asserted to notify the FSM when all the housekeeping tasks are completed. If the user chooses not to use housekeeping, the Flash*Freeze management IP core generator in Libero IDE will connect **WAIT_HOUSEKEEPING** to **DONE_HOUSEKEEPING**.

Clock Gating Block

Once DONE_HOUSEKEEPING is detected, the FSM will initiate the clock gating circuit by asserting ASSERT_GATE (active Low). ASSERT_GATE is named control_user_clock_net in the IP block. Upon assertion of the ASSERT_GATE signal, the clock will be gated in less than two cycles. The clock gating circuit is comprised of a flip-flop, latch, AND gate, and CLKINT, as shown in Figure 2-11. The clock gating block can support gating of up to 17 clocks.

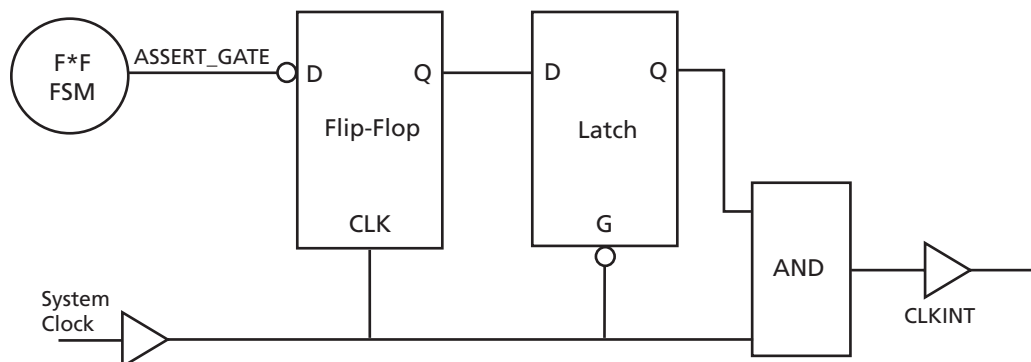

Figure 2-11 • Clock Gating Circuit

After initiating the clock gating circuit, the FSM will assert and hold the LSICC signal (active High), feeding the ULSICC macro. This will initiate the 1 μ s entrance into Flash*Freeze mode.

Upon deassertion of the Flash*Freeze pin, the FSM will set ASSERT_GATE High. Once the I/O banks become active, the clock will enter the device and register the ASSERT_GATE signal, cleanly releasing the clock gate.

Design Flow¹

Actel has developed a convenient and intuitive design flow for configuring and integrating Flash*Freeze technology into an FPGA design. Flash*Freeze type 1 is implemented by instantiating the INBUF_FF macro in the top level of a design. Flash*Freeze type 2 with management IP can be generated by the Libero IDE core generator or SmartGen and instantiated as a single block in the user's design. This single block will include an INBUF_FF macro and the optional Flash*Freeze management IP, which includes the ULSICC macro. If designers do not wish to use this core generator, the INBUF_FF macro and the optional ULSICC macro may be instantiated in the design, and custom Flash*Freeze management IP can be developed by the user. The remainder of this section will cover configuration details of the INBUF_FF macro, the ULSICC macro, and the Flash*Freeze management IP.

Additional information on the tools discussed within this section may be found in the Libero IDE online help.

INBUF_FF

The INBUF_FF macro is a special-purpose input buffer macro that is interpreted downstream in the design flow by Actel's Designer software. When this macro is used, the top-level port will be forced to the dedicated FF pin in the FPGA, and Flash*Freeze mode will be available for use in the device. The following are the design rules for INBUF_FF:

- If INBUF_FF is not used in the design, the device will not be configured to support Flash*Freeze mode.
- When the INBUF_FF macro is used, the FF pin will establish a hardwired connection to the Flash*Freeze technology circuit in the device, as shown in Figure 2-1 on page 2-5, Figure 2-3

1. This section applies to Libero IDE / Designer v8.3 and later. Actel recommends that designs created in earlier versions of the software be modified to accommodate this flow by instantiating the INBUF_FF macro or the Flash*Freeze management IP. Refer to the Libero IDE / Designer v8.3 release notes and the Libero IDE online help for more information on migrating designs from older software versions.

Figure 2-12 • FSM State Diagram

on page 2-6, and Figure 2-10 on page 2-16, and described in the "Flash*Freeze Type 1: Control by Dedicated Flash*Freeze Pin" section on page 2-4.

- The INBUF_FF must be driven by a top-level input port of the design.
- The INBUF_FF AND the ULSICC macro must be used to enable type 2 Flash*Freeze mode.
- For type 2 Flash*Freeze mode, the INBUF_FF MUST drive some logic in the design.
- For type 1 Flash*Freeze mode, the INBUF_FF may drive some logic in the design, but it may also be left floating.
- Only one INBUF_FF may be instantiated in a device.
- The FF pin threshold voltages are defined by V_{CCI} and the supported single-ended I/O standard in the corresponding I/O bank.
- The FF pin Schmitt trigger option may be configured in the I/O attribute editor in Actel's Designer software. The Schmitt trigger option is only available for IGLOOe, IGLOO nano, IGLOO PLUS, ProASIC3EL, and RT ProASIC3 devices.
- A 2 ns glitch filter resides in the Flash*Freeze Technology block to filter unwanted glitches on the FF pin.

ULSICC

The User Low Static ICC (ULSICC) macro allows the FPGA core to access the Flash*Freeze Technology block so that entering and exiting Flash*Freeze mode can be controlled by the user's design. The ULSICC macro enables a hard block with an available LSICC input port, as shown in [Figure 2-3 on page 2-6](#) and [Figure 2-10 on page 2-16](#). Design rules for the ULSICC macro are as follows:

- The ULSICC macro by itself cannot enable Flash*Freeze mode. The INBUF_FF AND the ULSICC macro must both be used to enable type 2 Flash*Freeze mode.
- The ULSICC controls entering the Flash*Freeze mode by asserting the LSICC input (logic '1') of the ULSICC macro. The FF pin must also be asserted (logic '0') to enter Flash*Freeze mode.
- When the LSICC signal is '0', the device cannot enter Flash*Freeze mode; and if already in Flash*Freeze mode, it will exit.
- When the ULSICC macro is not instantiated in the user's design, the LSICC port will be tied High.

Flash*Freeze Management IP

The Flash*Freeze management IP can be configured with the Libero IDE (or SmartGen) core generator in a simple, intuitive interface. With the core configuration tool, users can select the number of clocks to be gated, and select whether or not to implement housekeeping. All port names on the Flash*Freeze management IP block can be renamed by the user.

- The clock gating (filter) blocks include CLKINT buffers for each gated clock output (version 8.3).
- When housekeeping is NOT used, the WAIT_HOUSEKEEPING signal will be automatically fed back into DONE_HOUSEKEEPING inside the core, and the ports will not be available at the IP core interface.
- The INBUF_FF macro is automatically instantiated within the IP core.
- The INBUF_FF port (default name is "Flash_Freeze_N") must be connected to a top-level input port of the design.
- The ULSICC macro is automatically instantiated within the IP core, and the LSICC signal is driven by the FSM.
- Timing analysis can be performed on the clock domain of the source clock (i.e., input to the clock gating filters). For example, if CLKin becomes CLKin_gated, the timing can be performed on the CLKin domain in SmartTime.
- The gated clocks can be added to the clock list if the user wishes to analyze these clocks specifically. The user can locate the gated clocks by looking for instance names such as those below:

```
Top/ff1/ff_1_wrapper_inst/user_ff_1_wrapper/Primary_Filter_Instance/
Latch_For_Clock_Gating:Q
Top/ff1/ff_1_wrapper_inst/user_ff_1_wrapper/genblk1.genblk2.secondary_filter[0].
secondary_filter_instance/Latch_For_Clock_Gating:Q
Top/ff1/ff_1_wrapper_inst/user_ff_1_wrapper/genblk1.genblk2.secondary_filter[1].
secondary_filter_instance/Latch_For_Clock_Gating:Q
```

- There will be added skew and clock insertion delay due to the clock gating circuit. The user should analyze external setup/hold times carefully. The user should also ensure the additional skew across the clock gating filter circuit is accounted for in any paths where the launch register is driven from the filter input clock and captured by a register driven by the gated clock filter output clock.

Power Analysis

SmartPower identifies static and dynamic power consumption problems quickly within a design. It provides a hierarchical view, allowing users to drill down and estimate the power consumption of individual components or events. SmartPower analyzes power consumption for nets, gates, I/Os, memories, clocks, cores, clock domains, power supply rails, peak power during a clock cycle, and switching transitions.

SmartPower generates detailed hierarchical reports of the dynamic power consumption of a design for easy inspection. These reports include design-level power summary, average switching activity, and ambient and junction temperature readings. Enter the target clock and data frequencies for a design, and let SmartPower perform a detailed and accurate power analysis. SmartPower supports importing files in the VCD (Value-Change Dump) format as specified in the IEEE 1364 standard. It also supports the Synopsys® Switching Activity Interchange Format (SAIF) standard. Support for these formats lets designers generate switching activity information in a variety of simulators and then import this information directly into SmartPower.

For portable or battery-operated applications, a power profile feature enables you to measure power and battery life, based on a sequence of operational modes of the design. In most portable and battery-operated applications, the system is seldom fully "on" 100 percent of the time. "On" is a combination of fully active, standby, sleep, or other functional modes. SmartPower allows users to create a power profile for a design by specifying operational modes and the percent of time the device will run in each of the modes. Power is calculated for each of the modes, and total power is calculated based on the weighted average of all modes.

SmartPower also provides an estimated battery life based on the power profile. The current capacity for a given battery is entered and used to estimate the life of the battery. The result is an accurate and realistic indication of battery life.

More information on SmartPower can be found on the Actel website:
<http://www.actel.com/products/software/libero/smartpower.aspx>.

Additional Power Conservation Techniques

IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 FPGAs provide many ways to inherently conserve power; however, there are also several design techniques that can be used to reduce power on the board.

- Actel recommends that the designer use the minimum number of I/O banks possible and tie any unused power supplies (such as V_{CCPLL} , V_{CCI} , V_{MV} , and V_{PUMP}) to ground.
- Leave unused I/O ports floating. Unused I/Os are configured by the software as follows:
 - Output buffer is disabled (with tristate value of high impedance)
 - Input buffer is disabled (with tristate value of high impedance)
- Use the lowest available voltage I/O standard, the lowest drive strength, and the slowest slew rate to reduce I/O switching contribution to power consumption.
- Advanced and pro I/O banks may consume slightly higher static current than standard and standard plus banks—avoid using advanced and pro banks whenever practical.
 - The small static power benefit obtained by avoiding advanced or pro I/O banks is usually negligible compared to the benefit of using a low-power I/O standard.
- Deselect RAM blocks that are not being used.
- Only enable read and write ports on RAM blocks when they are needed.
- Gating clocks LOW offers improved static power of RAM blocks.
- Drive the FF port of RAM blocks with the Flash_Freeze_Enabled signal from the Flash*Freeze management IP.
- Drive inputs to the full voltage level so that all transistors are turned on or off completely.
- Avoid using pull-ups and pull-downs on I/Os because these resistors draw some current. Avoid driving resistive loads or bipolar transistors, since these draw a continuous current, thereby adding to the static current.
- When partitioning the design across multiple devices, minimize I/O usage among the devices.

Conclusion

Actel IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 family architectures are designed to achieve ultra-low power consumption based on enhanced nonvolatile and live-at-power-up flash-based technology. Power consumption can be reduced further by using Flash*Freeze, Static (Idle), Sleep, and Shutdown power modes. All these features result in a low-power, cost-effective, single-chip solution designed specifically for power-sensitive and battery-operated electronics applications.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

Part Number 51700094-004-6

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v2.2)	Page
v2.1 (October 2008)	IGLOO nano devices were added as a supported family.	N/A
	The "Prototyping for IGLOO and ProASIC3L Devices Using ProASIC3" section was removed, as these devices are now in production.	N/A
	The "Additional Power Conservation Techniques" section was revised to add RT ProASIC3 devices.	2-20
v2.0 (October 2008)	The "Flash*Freeze Management FSM" section was updated with the following information: The FSM also asserts Flash_Freeze_Enabled whenever the device enters Flash*Freeze mode. This occurs after all housekeeping and clock gating functions have completed.	2-16
v1.3 (June 2008)	The title changed from "Flash*Freeze Technology and Low-Power Modes in IGLOO, IGLOO PLUS, and ProASIC3L Devices" to Actel's Flash*Freeze Technology and Low-Power Modes."	N/A
	The "Actel's Flash Families Support the Flash*Freeze Feature" section was updated.	2-2
	Significant changes were made to this document to support Libero IDE v8.4 and later functionality. RT ProASIC3 device support information is new. In addition to the other major changes, the following tables and figures were updated or are new: Figure 2-3 · Flash*Freeze Mode Type 2 – Controlled by Flash*Freeze Pin and Internal Logic (LSICC signal) – updated Figure 2-5 · Narrow Clock Pulses During Flash*Freeze Entrance and Exit – new Figure 2-10 · Flash*Freeze Management IP Block Diagram – new Figure 2-12 · FSM State Diagram – new Table 2-6 · IGLOO nano and IGLOO PLUS Flash*Freeze Mode (type 1 and type 2)—I/O Pad State – updated Please review the entire document carefully.	2-6 2-9 2-16 2-18 2-8
v1.2 (March 2008)	The family description for ProASIC3L in Table 2-1 · Flash-Based FPGAs was updated to include 1.5 V.	2-2
v1.1 (February 2008)	The part number for this document was changed from 51700094-003-1 to 51700094-004-2.	N/A
	The title of the document was changed to "Flash*Freeze Technology and Low-Power Modes in IGLOO, IGLOO PLUS, and ProASIC3L Devices."	N/A
	The "Flash*Freeze Technology and Low-Power Modes" section was updated to remove the parenthetical phrase, "from 25 μ W," in the second paragraph. The following sentence was added to the third paragraph: "IGLOO PLUS has an additional feature when operating in Flash*Freeze mode, allowing it to retain I/O states as well as SRAM and register states."	2-1
	The "Power Conservation Techniques" section was updated to add V _{JTAG} to the parenthetical list of power supplies that should be tied to the ground plane if unused. Additional information was added regarding how the software configures unused I/Os.	2-1
	Table 2-1 · Flash-Based FPGAs and the accompanying text was updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "ProASIC3 Terminology" section are new.	2-2

Previous Version	Changes in Current Version (v2.2)	Page
v1.1 (continued)	The "Flash*Freeze Mode" section was revised to include that I/O states are preserved in Flash*Freeze mode for IGLOO PLUS devices. The last sentence in the second paragraph was changed to, "If the FF pin is not used, it can be used as a regular I/O." The following sentence was added for Flash*Freeze mode type 2: "Exiting the mode is controlled by either the FF pin OR the user-defined LSICC signal."	2-4
	The "Flash*Freeze Type 1: Control by Dedicated Flash*Freeze Pin" section was revised to change instructions for implementing this mode, including instructions for implementation with Libero IDE v8.3.	2-4
	Figure 2-1 · Flash*Freeze Mode Type 1 – Controlled by the Flash*Freeze Pin was updated.	2-5
	The "Flash*Freeze Type 2: Control by Dedicated Flash*Freeze Pin and Internal Logic" section was renamed from "Type 2 Software Implementation."	2-6
	The "Type 2 Software Implementation for Libero IDE v8.3" section is new.	2-6
	Figure 2-3 · Flash*Freeze Mode Type 2 – Controlled by Flash*Freeze Pin and Internal Logic (LSICC signal) was updated.	2-6
	Figure 2-4 · Flash*Freeze Mode Type 2 – Timing Diagram was revised to show deasserting LSICC after the device has exited Flash*Freeze mode.	2-7
	The "IGLOO nano and IGLOO PLUS I/O State in Flash*Freeze Mode" section was added to include information for IGLOO PLUS devices. Table 2-6 · IGLOO nano and IGLOO PLUS Flash*Freeze Mode (type 1 and type 2)—I/O Pad State is new.	2-7, 2-8
	The "During Flash*Freeze Mode" section was revised to include a new bullet pertaining to output behavior for IGLOO PLUS. The bullet on JTAG operation was revised to provide more detail.	2-10
	Figure 2-6 · Controlling Power-On/-Off State Using Microprocessor and Power FET and Figure 2-7 · Controlling Power-On/-Off State Using Microprocessor and Voltage Regulator were updated to include IGLOO PLUS.	2-12, 2-12
	The first sentence of the "Shutdown Mode" section was updated to list the devices for which it is supported.	2-11
	The first paragraph of the "Power-Up/-Down Behavior" section was revised. The second sentence was changed to, "The I/Os remain tristated until the last voltage supply (V _{CC} or V _{CC1}) is powered to its activation level." The word "activation" replaced the word "functional." The sentence, "During power-down, device I/Os become tristated once the first power supply (V _{CC} or V _{CC1}) drops below its deactivation voltage level" was revised. The word "deactivation" replaced the word "brownout."	2-12
	The "Prototyping for IGLOO and ProASIC3L Devices Using ProASIC3" section was revised to state that prototyping in ProASIC3 does not apply for the IGLOO PLUS family.	2-21
Table 2-8 · Prototyping/Migration Solutions, Table 2-9 · Device Migration—IGLOO Supported Packages in ProASIC3 Devices, and Table 2-10 · Device Migration—ProASIC3L Supported Packages in ProASIC3 Devices were updated with a table note stating that device migration is not supported for IGLOO PLUS devices.	2-21, 2-23	
The text following Table 2-10 · Device Migration—ProASIC3L Supported Packages in ProASIC3 Devices was moved to a new section: the "Flash*Freeze Design Guide" section.	2-13	

Previous Version	Changes in Current Version (v2.2)	Page
v1.0 (January 2008)	Table 2-1 · Flash-Based FPGAs was updated to remove the ProASIC3, ProASIC3E, and Automotive ProASIC3 families, which were incorrectly included.	2-2
51900147-2/5.07	Detailed descriptions of low-power modes are described in the advanced datasheets. This application note was updated to describe how to use the features in an IGLOO/e application.	N/A
	Figure 2-1 · Flash*Freeze Mode Type 1 – Controlled by the Flash*Freeze Pin was updated.	2-5
	Figure 2-2 · Flash*Freeze Mode Type 1 – Timing Diagram is new.	2-5
	Steps 4 and 5 are new in the "Flash*Freeze Type 2: Control by Dedicated Flash*Freeze Pin and Internal Logic" section.	2-6
51900147-1/3.07	In the following sentence, located in the "Flash*Freeze Mode" section, the bold text was changed from active high to active Low. The Flash*Freeze pin (active low) is a dedicated pin used to enter or exit Flash*Freeze mode directly, or alternatively the pin can be routed internally to the FPGA core to allow the user's logic to decide if it is safe to transition to this mode.	2-4
	Figure 2-2 · Flash*Freeze Mode Type 1 – Timing Diagram was updated.	2-5
	Information about ULSICC was added to the "Prototyping for IGLOO and ProASIC3L Devices Using ProASIC3" section.	2-21
51900147-0/8.06	In the "Flash*Freeze Mode" section, "active high" was changed to "active low."	2-4
	The "Prototyping for IGLOO and ProASIC3L Devices Using ProASIC3" section was updated with information concerning the Flash*Freeze pin.	2-21

Global Resources and Clock Conditioning

3 – Global Resources in Actel Low-Power Flash Devices

Introduction

Actel IGLOO®, Fusion, and ProASIC®3 FPGA devices offer a powerful, low-delay VersaNet global network scheme and have extensive support for multiple clock domains. In addition to the Clock Conditioning Circuits (CCCs) and phase-locked loops (PLLs), there is a comprehensive global clock distribution network called a VersaNet global network. Each logical element (VersaTile) input and output port has access to these global networks. The VersaNet global networks can be used to distribute low-skew clock signals or high-fanout nets. In addition, these highly segmented VersaNet global networks offer users the flexibility to create low-skew local networks using spines. This document describes VersaNet global networks and discusses how to assign signals to these global networks and spines in a design flow. Details concerning low-power flash device PLLs are described in *Clock Conditioning Circuits in IGLOO and ProASIC3 Devices*. This document describes the low-power flash devices' global architecture and uses of these global networks in designs.

Global Architecture

Low-power flash devices offer powerful and flexible control of circuit timing through the use of analog circuitry. Each chip has up to six CCCs, some with PLLs.

- In IGLOOe, ProASIC3EL, and ProASIC3E devices, all CCCs have PLLs—hence, 6 PLLs per device.
- In IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3, and ProASIC3L devices, the west CCC contains a PLL core (except in 10 k through 30 k devices).
- In Fusion devices, the west CCC also contains a PLL core. In the two larger devices (AFS600 and AFS1500), the west and east CCCs each contain a PLL.

Each PLL includes delay lines, a phase shifter (0°, 90°, 180°, 270°), and clock multipliers/dividers. Each CCC has all the circuitry needed for the selection and interconnection of inputs to the VersaNet global network. The east and west CCCs each have access to three VersaNet global lines on each side of the chip (six global lines total). The CCCs at the four corners each have access to three quadrant global lines in each quadrant of the chip (except in 10 k through 30 k gate devices). The nano 10 k, 15 k, and 20 k devices support four VersaNet global resources, and 30 k devices support six global resources. The 10 k through 30 k devices have simplified CCCs called CCC-GLs.

The flexible use of the VersaNet global network allows the designer to address several design requirements. User applications that are clock-resource-intensive can easily route external or gated internal clocks using VersaNet global routing networks. Designers can also drastically reduce delay penalties and minimize resource usage by mapping critical, high-fanout nets to the VersaNet global network.

The following sections give an overview of the VersaNet global network, the structure of the global network, and the clock aggregation feature that enables a design to have very low clock skew using spines.

Global Resource Support in Flash-Based Devices

The flash FPGAs listed in [Table 3-1](#) support the global resources and the functions described in this document.

Table 3-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
	IGLOO nano	The industry's lowest-power, smallest-size solution
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO products as listed in [Table 3-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 3-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

VersaNet Global Network Distribution

One of the architectural benefits of low-power flash architecture is the set of powerful, low-delay VersaNet global networks that can access the VersaTiles, SRAM, and I/O tiles of the device. Each device offers a chip global network with six global lines (except for nano 10 k, 15 k, and 20 k gate devices) that are distributed from the center of the FPGA array. In addition, each device (except the 10 k through 30 k gate device) has four quadrant global networks, each with three regional global line resources. These quadrant global networks can only drive a signal inside their own quadrant. Each core VersaTile has access to nine global line resources—three quadrant and six chip-wide (main) global networks—and a total of 18 globals are available on the device (3 × 4 regional from each quadrant and 6 global).

Figure 3-1 shows an overview of the VersaNet global network and device architecture for devices 60 k and above. Figure 3-2 and Figure 3-3 on page 3-4 show simplified VersaNet global networks.

The VersaNet global networks are segmented and consist of VersaNet global networks, spines, global ribs, and global multiplexers (MUXes), as shown in Figure 3-1. The global networks are driven from the global rib at the center of the die or quadrant global networks at the north or south side of the die. The global network uses the MUX trees to access the spine, and the spine uses the clock ribs to access the VersaTile. Access is available to the chip or quadrant global networks and the spines through the global MUXes. Access to the spine using the global MUXes is explained in the "Spine Architecture" section on page 3-5.

These VersaNet global networks offer fast, low-skew routing resources for high-fanout nets, including clock signals. In addition, these highly segmented global networks offer users the flexibility to create low-skew local networks using spines for up to 252 internal/external clocks or other high-fanout nets in low-power flash devices. Optimal usage of these low-skew networks can result in significant improvement in design performance.

Note: Not applicable to 10 k through 30 k gate devices

Figure 3-1 • Overview of VersaNet Global Network and Device Architecture

Figure 3-2 • Simplified VersaNet Global Network (30 k gates and below)

Figure 3-3 • Simplified VersaNet Global Network (60 k gates and above)

Spine Architecture

The low-power flash device architecture allows the VersaNet global networks to be segmented. Each of these networks contains spines (the vertical branches of the global network tree) and ribs that can reach all the VersaTiles inside its region. The nine spines available in a vertical column reside in global networks with two separate regions of scope: the quadrant global network, which has three spines, and the chip (main) global network, which has six spines. Note that the number of quadrant globals and globals/spines per tree varies depending on the specific device. Refer to [Table 3-2 on page 3-6](#) for the clocking resources available for each device. The spines are the vertical branches of the global network tree, shown in [Figure 3-3](#). Each spine in a vertical column of a chip (main) global network is further divided into two spine segments of equal lengths: one in the top and one in the bottom half of the die (except in 10 k through 30 k gate devices).

Top and bottom spine segments radiating from the center of a device have the same height. However, just as in the ProASIC^{PLUS}® family, signals assigned only to the top and bottom spine cannot access the middle two rows of the die. The spines for quadrant clock networks do not cross the middle of the die and cannot access the middle two rows of the architecture.

Each spine and its associated ribs cover a certain area of the device (the "scope" of the spine; see [Figure 3-3](#)). Each spine is accessed by the dedicated global network MUX tree architecture, which defines how a particular spine is driven—either by the signal on the global network from a CCC, for example, or by another net defined by the user. Details of the chip (main) global network spine-selection MUX are presented in [Figure 3-5 on page 3-8](#). The spine drivers for each spine are located in the middle of the die.

Quadrant spines can be driven from user I/Os on the north and south sides of the die. The ability to drive spines in the quadrant global networks can have a significant effect on system performance for high-fanout inputs to a design. Access to the top quadrant spine regions is from the top of the die, and access to the bottom quadrant spine regions is from the bottom of the die. The A3PE3000 device has 28 clock trees and each tree has nine spines; this flexible global network architecture enables users to map up to 252 different internal/external clocks in an A3PE3000 device.

Table 3-2 • Globals/Spines/Rows for IGLOO and ProASIC3 Devices

ProASIC3/ ProASIC3L Devices	IGLOO Devices	Chip Globals	Quadrant Globals (4x3)	Clock Trees	Globals/ Spines per Tree	Total Spines per Device	VersaTiles in Each Tree	Total VersaTiles	Rows in Each Spine
A3PN010	AGLN010	4	0	1	0	0	260	260	4
A3PN015	AGLN015	4	0	1	0	0	384	384	6

*Note: *Clock trees that are located at far left and far right will support more VersaTiles.*

Table 3-4 • Globals/Spines/Rows for Fusion Devices

Fusion Device	Chip Globals	Quadrant Globals (4x3)	Clock Trees	Globals/ Spines per Tree	Total Spines per Device	VersaTiles in Each Tree	Total VersaTiles	Rows in Each Spine
AFS090	6	12	6	9	54	384	2,304	12
AFS250	6	12	8	9	72	768	6,144	24
AFS600	6	12	12	9	108	1,152	13,824	36
AFS1500	6	12	20	9	180	1,920	38,400	60

Spine Access

The physical location of each spine is identified by the letter 'T' (top) or 'B' (bottom) and an accompanying number (T_n or B_n). The number n indicates the horizontal location of the spine; 1 refers to the first spine on the left side of the die. Since there are six chip spines in each spine tree, there are up to six spines available for each combination of 'T' (or 'B') and n (for example, six T1 spines). Similarly, there are three quadrant spines available for each combination of 'T' (or 'B') and n (for example, four T1 spines), as shown in [Figure 3-4](#).

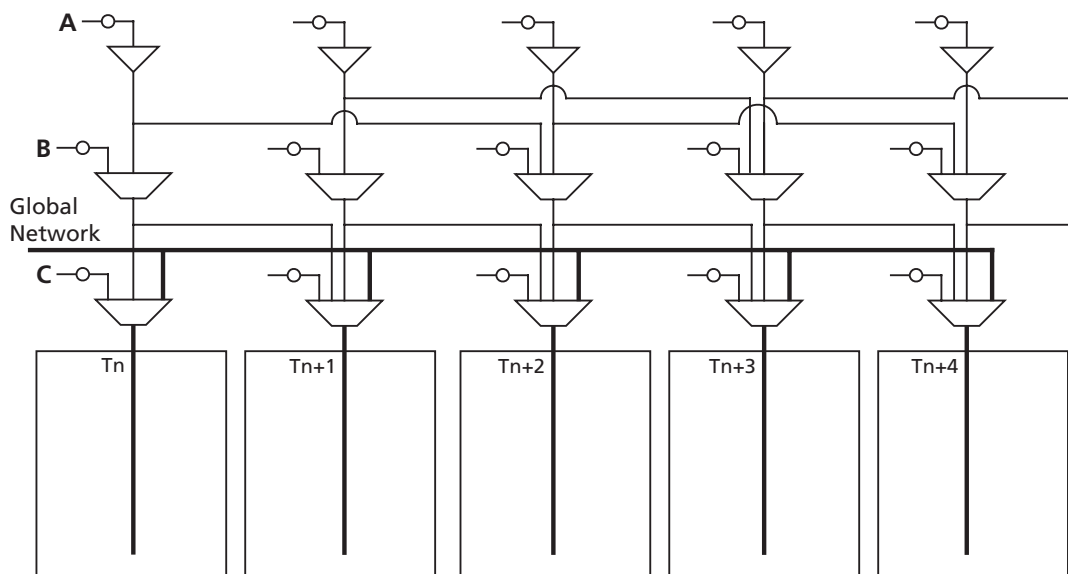

Figure 3-4 • Chip Global Aggregation

Spines are also called local clocks, and are accessed by the dedicated global MUX architecture. These MUXes define how a particular spine is driven. Refer to [Figure 3-5 on page 3-8](#) for the global MUX architecture. The MUXes for each chip global spine are located in the middle of the die. Access to the top and bottom chip global spine is available from the middle of the die. There is no control dependency between the top and bottom spines. If a top spine, T1, of a chip global network is assigned to a net, B1 is not wasted and can be used by the global clock network. The signal assigned only to the top or bottom spine cannot access the middle two rows of the architecture. However, if a spine is using the top and bottom at the same time (T1 and B1, for instance), the previous restriction is lifted.

The MUXes for each quadrant global spine are located in the north and south sides of the die. Access to the top and bottom quadrant global spines is available from the north and south sides of the die. Since the MUXes for quadrant spines are located in the north and south sides of the die, you should not try to drive T1 and B1 quadrant spines from the same signal.

Using Clock Aggregation

Clock aggregation allows for multi-spine clock domains to be assigned using hardwired connections, without adding any extra skew. A MUX tree, shown in Figure 3-5, provides the necessary flexibility to allow long lines, local resources, or I/Os to access domains of one, two, or four global spines. Signal access to the clock aggregation system is achieved through long-line resources in the central rib in the center of the die, and also through local resources in the north and south ribs, allowing I/Os to feed directly into the clock system. As Figure 3-6 indicates, this access system is contiguous.

There is no break in the middle of the chip for the north and south I/O VersaNet access. This is different from the quadrant clocks located in these ribs, which only reach the middle of the rib.

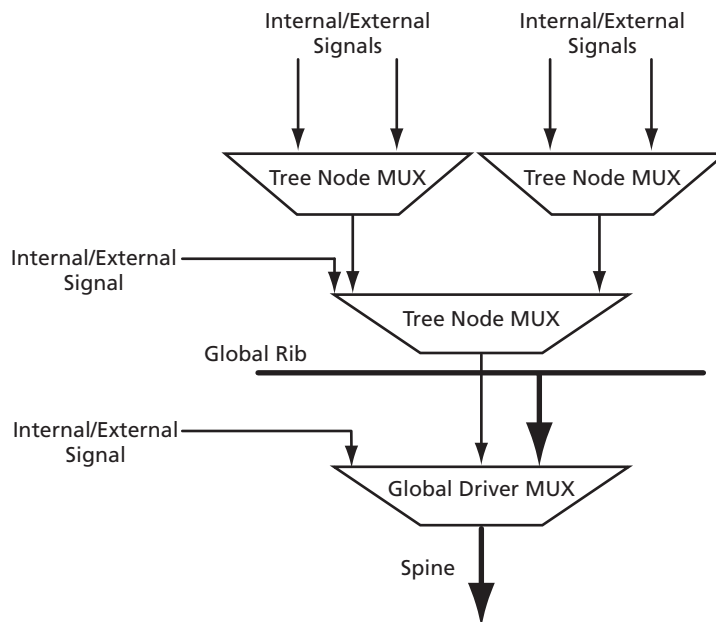

Figure 3-5 • Spine Selection MUX of Global Tree

Figure 3-6 • Clock Aggregation Tree Architecture

Clock Aggregation Architecture

This clock aggregation feature allows a balanced clock tree, which improves clock skew. The physical regions for clock aggregation are defined from left to right and shift by one spine. For chip global networks, there are three types of clock aggregation available, as shown in Figure 3-7:

- Long lines that can drive up to four adjacent spines
- Long lines that can drive up to two adjacent spines
- Long lines that can drive one spine

There are three types of clock aggregation available for the quadrant spines, as shown in Figure 3-7:

- I/Os or local resources that can drive up to four adjacent spines
- I/Os or local resources that can drive up to two adjacent spines
- I/Os or local resources that can drive one spine
- As an example, A3PE600 and AFS600 devices have twelve spine locations: T1, T2, T3, T4, T5, T6, B1, B2, B3, B4, B5, and B6. Table 3-5 shows the clock aggregation you can have in A3PE600 and AFS600.

Figure 3-7 • Four Spines Aggregation

Table 3-5 • Spine Aggregation in A3PE600 or AFS600

Clock Aggregation	Spine
1 spine	T1, T2, T3, T4, T5, T6, B1, B2, B3, B4, B5, B6
2 spines	T1:T2, T2:T3, T3:T4, T4:T5, T5:T6, B1:B2, B2:B3, B3:B4, B4:B5, B5:B6
4 spines	B1:B4, B2:B5, B3:B6, T1:T4, T2:T5, T3:T6

The clock aggregation for the quadrant spines can cross over from the left to right quadrant, but not from top to bottom. The quadrant spine assignment T1:T4 is legal, but the quadrant spine assignment T1:B1 is not legal. Note that this clock aggregation is hardwired. You can always assign signals to spine T1 and B2 by instantiating a buffer, but this may add skew in the signal.

I/O Banks and Global I/Os

The following sections give an overview of naming conventions and other related I/O information.

Naming of Global I/Os

In low-power flash devices, the global I/Os have access to certain clock conditioning circuitry and have direct access to the global network. Additionally, the global I/Os can be used as regular I/Os, since they have identical capabilities to those of regular I/Os. Due to the comprehensive and flexible nature of the I/Os in low-power flash devices, a naming scheme is used to show the details of the I/O. The global I/O uses the generic name Gmn/IOuxwByVz. Refer to the I/O Structure section of the handbook for the device that you are using for more information on this naming convention.

Figure 3-8 represents the global input pins connection to the northwest CCC or northwest quadrant global networks for a low-power flash device. Each global buffer, as well as the PLL reference clock, can be driven from one of the following:

- 3 dedicated single-ended I/Os using a hardwired connection
- 2 dedicated differential I/Os using a hardwired connection
- The FPGA core

Since each bank can have a different I/O standard, the user should be careful to choose the correct global I/O for the design. There are 54 global pins available to access 18 global networks. For the single-ended and voltage-referenced I/O standards, you can use any of these three available I/Os to access the global network. For differential I/O standards such as LVDS and LVPECL, the I/O macro needs to be placed on GAA0 and GAA1 or a similar location. The unassigned global I/Os can be used as regular I/Os. Note that pin names starting with GF and GC are associated with the chip global networks, and GA, GB, GD, and GE are used for quadrant global networks.

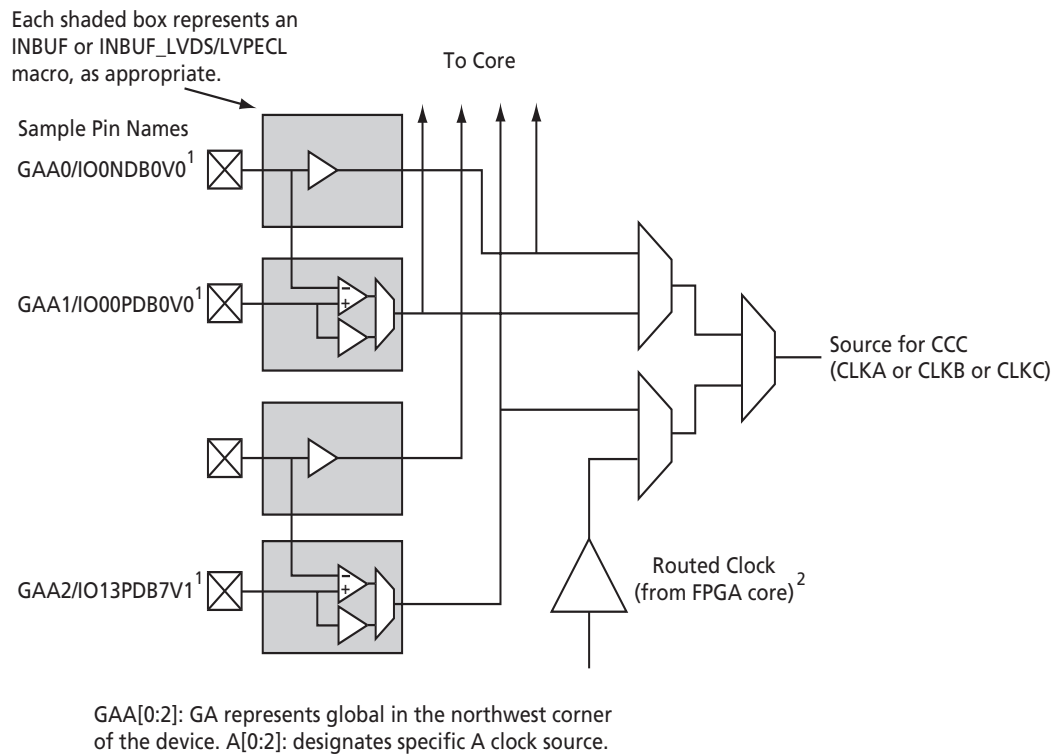

Figure 3-8 • Global I/O Overview

Unused Global I/O Configuration

The unused clock inputs behave similarly to the unused Pro I/Os. The Actel Designer software automatically configures the unused global pins as inputs with pull-up resistors if they are not used as regular I/O.

I/O Banks and Global I/O Standards

In low-power flash devices, any I/O or internal logic can be used to drive the global network. However, only the global macro placed at the global pins will use the hardwired connection between the I/O and global network. Global signal (signal driving a global macro) assignment to I/O banks is no different from regular I/O assignment to I/O banks with the exception that you are limited to the pin placement location available. Only global signals compatible with both the V_{CCI} and V_{REF} standards can be assigned to the same bank.

Design Recommendations

The following sections provide design flow recommendations for using a global network in a design.

- "Global Macros and I/O Standards"
- "Using Global Macros in Synplicity" on page 3-13
- "Global Promotion and Demotion Using PDC" on page 3-14
- "Spine Assignment" on page 3-15
- "Designer Flow for Global Assignment" on page 3-16
- "Simple Design Example" on page 3-18
- "Global Management in PLL Design" on page 3-20
- "Using Spines of Occupied Global Networks" on page 3-21

Global Macros and I/O Standards

Low-power flash devices have six chip global networks and four quadrant clock networks. However, the same clock macros are used for assigning signals to chip globals and quadrant globals. Depending on the clock macro placement or assignment in the Physical Design Constraint (PDC) file or MultiView Navigator (MVN), the signal will use the chip global network or quadrant network. Table 3-6 on page 3-12 lists the clock macros available for low-power flash devices. Refer to the *IGLOO, Fusion and ProASIC3 Macro Library Guide* for details.

Table 3-6 • Clock Macros

Macro Name	Description	Symbol
CLKBUF	Input macro for Clock Network	
CLKBUF_x	Input macro for Clock Network with specific I/O standard	
CLKBUF_LVDS/ LVPECL	LVDS or LVPECL input macro for Clock Network	
CLKINT	Internal clock interface	
CLKBIBUF	Bidirectional macro with input dedicated to routed Clock Network	

Use these available macros to assign a signal to the global network. In addition to these global macros, PLL and CLKDLY macros can also drive the global networks. Use I/O-standard-specific clock macros (CLKBUF_x) to instantiate a specific I/O standard for the global signals. Table 3-7 shows the list of these I/O-standard-specific macros. Note that if you use these I/O-standard-specific clock macros, you cannot change the I/O standard later in the design stage. If you use the regular CLKBUF macro, you can use MVN or the PDC file in Designer to change the I/O standard. The default I/O standard for CLKBUF is LVTTTL in the current Actel Libero® Integrated Design Environment (IDE) and Designer software.

Table 3-7 • I/O Standards within CLKBUF

Name	Description
CLKBUF_LVCMOS5	LVC MOS clock buffer with 5.0 V CMOS voltage level
CLKBUF_LVCMOS33	LVC MOS clock buffer with 3.3 V CMOS voltage level
CLKBUF_LVCMOS25	LVC MOS clock buffer with 2.5 V CMOS voltage level ¹
CLKBUF_LVCMOS18	LVC MOS clock buffer with 1.8 V CMOS voltage level
CLKBUF_LVCMOS15	LVC MOS clock buffer with 1.5 V CMOS voltage level
CLKBUF_LVCMOS12	LVC MOS clock buffer with 1.2 V CMOS voltage level
CLKBUF_PCI	PCI clock buffer
CLKBUF_PCIX	PCIX clock buffer
CLKBUF_GTL25	GTL clock buffer with 2.5 V CMOS voltage level ¹
CLKBUF_GTL33	GTL clock buffer with 3.3 V CMOS voltage level ¹

Notes:

1. Supported in only the IGLOOe, ProASIC3E, AFS600, and AFS1500 devices
2. By default, the CLKBUF macro uses the 3.3 V LVTTTL I/O technology.

Table 3-7 • I/O Standards within CLKBUF (continued)

Name	Description
CLKBUF_GTL25	GTL+ clock buffer with 2.5 V CMOS voltage level ¹
CLKBUF_GTL33	GTL+ clock buffer with 3.3 V CMOS voltage level ¹
CLKBUF_HSTL_I	HSTL Class I clock buffer ¹
CLKBUF_HSTL_II	HSTL Class II clock buffer ¹
CLKBUF_SSTL2_I	SSTL2 Class I clock buffer ¹
CLKBUF_SSTL2_II	SSTL2 Class II clock buffer ¹
CLKBUF_SSTL3_I	SSTL3 Class I clock buffer ¹
CLKBUF_SSTL3_II	SSTL3 Class II clock buffer ¹

Notes:

1. Supported in only the IGLOOe, ProASIC3E, AFS600, and AFS1500 devices
2. By default, the CLKBUF macro uses the 3.3 V LVTTTL I/O technology.

The current synthesis tool libraries only infer the CLKBUF or CLKINT macros in the netlist. All other global macros must be instantiated manually into your HDL code. The following is an example of CLKBUF_LVCMOS25 global macro instantiations that you can copy and paste into your code:

VHDL

```
component clkbuf_lvcmos25
  port (pad : in std_logic; y : out std_logic);
end component

begin
  -- concurrent statements
  u2 : clkbuf_lvcmos25 port map (pad => ext_clk, y => int_clk);
end
```

Verilog

```
module design (____);

  input ____;
  output ____;

  clkbuf_lvcmos25 u2 (.y(int_clk), .pad(ext_clk));

endmodule
```

Using Global Macros in Synplicity

The Synplify® synthesis tool automatically inserts global buffers for nets with high fanout during synthesis. By default, Synplicity® puts six global macros (CLKBUF or CLKINT) in the netlist, including any global instantiation or PLL macro. Synplify always honors your global macro instantiation. If you have a PLL (only primary output is used) in the design, Synplify adds five more global buffers in the netlist. Synplify uses the following global counting rule to add global macros in the netlist:

1. CLKBUF: 1 global buffer
2. CLKINT: 1 global buffer
3. CLKDLY: 1 global buffer
4. PLL: 1 to 3 global buffers
 - GLA, GLB, GLC, YB, and YC are counted as 1 buffer.
 - GLB or YB is used or both are counted as 1 buffer.
 - GLC or YC is used or both are counted as 1 buffer.

Note: OADIVRST exists only in the Fusion PLL.

Figure 3-9 • PLLs in Low-Power Flash Devices

You can use the `syn_global_buffers` attribute in Synplify to specify a maximum number of global macros to be inserted in the netlist. This can also be used to restrict the number of global buffers inserted. In the Synplicity 8.1 version, a new attribute, `syn_global_minfanout`, has been added for low-power flash devices. This enables you to promote only the high-fanout signal to global. However, be aware that you can only have six signals assigned to chip global networks, and the rest of the global signals should be assigned to quadrant global networks. So, if the netlist has 18 global macros, the remaining 12 global macros should have fanout that allows the instances driven by these globals to be placed inside a quadrant.

Global Promotion and Demotion Using PDC

The HDL source file or schematic is the preferred place for defining which signals should be assigned to a clock network using clock macro instantiation. This method is preferred because it is guaranteed to be honored by the synthesis tools and Designer software and stop any replication on this net by the synthesis tool. Note that a signal with fanout may have logic replication if it is not promoted to global during synthesis. In that case, the user cannot promote that signal to global using PDC. See Synplicity Help for details on using this attribute. To help you with global management, Designer allows you to promote a signal to a global network or demote a global macro to a regular macro from the user netlist using the compile options and/or PDC commands.

The following are the PDC constraints you can use to promote a signal to a global network:

1. PDC syntax to promote a regular net to a chip global clock:

```
assign_global_clock -net netname
```

The following will happen during promotion of a regular signal to a global network:

- If the net is external, the net will be driven by a CLKINT inserted automatically by Compile.
- The I/O macro will not be changed to CLKBUF macros.
- If the net is an internal net, the net will be driven by a CLKINT inserted automatically by Compile.

2. PDC syntax to promote a net to a quadrant clock:

```
assign_local_clock -net netname -type quadrant UR|UL|LR|LL
```

This follows the same rule as the chip global clock network.

The following PDC command demotes the clock nets to regular nets.

```
unassign_global_clock -net netname
```

The following will happen during demotion of a global signal to regular nets:

- CLKBUF_x becomes INBUF_x; CLKINT is removed from the netlist.
- The essential global macro, such as the output of the Clock Conditioning Circuit, cannot be demoted.
- No automatic buffering will happen.

Since no automatic buffering happens when a signal is demoted, this net may have a high delay due to large fanout. This may have a negative effect on the quality of the results. Actel recommends that the automatic global demotion only be used on small-fanout nets. Use clock networks for high-fanout nets to improve timing and routability.

Spine Assignment

The low-power flash device architecture allows the global networks to be segmented and used as clock spines. These spines, also called local clocks, enable the use of PDC or MVN to assign a signal to a spine.

PDC syntax to promote a net to a spine/local clock:

```
assign_local_clock -net netname -type [quadrant|chip] Tn|Bn|Tn:Bm
```

If the net is driven by a clock macro, Designer automatically demotes the clock net to a regular net before it is assigned to a spine. Nets driven by a PLL or CLKDLY macro cannot be assigned to a local clock.

When assigning a signal to a spine or quadrant global network using PDC (pre-compile), the Designer software will legalize the shared instances. The number of shared instances to be legalized can be controlled by compile options. If these networks are created in MVN (only quadrant globals can be created), no legalization is done (as it is post-compile). Designer does not do legalization between non-clock nets.

As an example, consider two nets, net_clk and net_reset, driving the same flip-flop. The following PDC constraints are used:

```
assign_local_clock -net net_clk -type chip T3
assign_local_clock -net net_reset -type chip T1:T2
```

During Compile, Designer adds a buffer in the reset net and places it in the T1 or T2 region, and places the flip-flop in the T3 spine region (Figure 3-10).

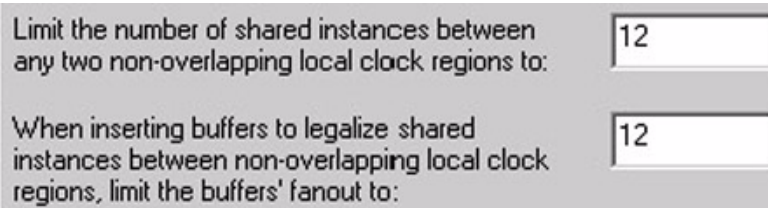

Figure 3-10 • Adding a Buffer for Shared Instances

You can control the maximum number of shared instances allowed for the legalization to take place using the Compile Option dialog box shown in [Figure 3-11](#). Refer to Libero IDE / Designer online help for details on the Compile Option dialog box. A large number of shared instances most likely indicates a floorplanning problem that you should address.

The image shows a portion of the Compile Option dialog box with two settings:

- Limit the number of shared instances between any two non-overlapping local clock regions to: 12
- When inserting buffers to legalize shared instances between non-overlapping local clock regions, limit the buffers' fanout to: 12

Figure 3-11 • Shared Instances in the Compile Option Dialog Box

Designer Flow for Global Assignment

To achieve the desired result, pay special attention to global management during synthesis and place-and-route. The current Synplify tool does not insert more than six global buffers in the netlist by default. Thus, the default flow will not assign any signal to the quadrant global network. However, you can use attributes in Synplify and increase the default global macro assignment in the netlist. Designer v6.2 supports automatic quadrant global assignment, which was not available in Designer v6.1. Layout will make the choice to assign the correct signals to global. However, you can also utilize PDC and perform manual global assignment to overwrite any automatic assignment. The following step-by-step suggestions guide you in the layout of your design and help you improve timing in Designer:

1. Run Compile and check the Compile report. The Compile report has global information in the "Device Utilization" section that describes the number of chip and quadrant signals in the design. A "Net Report" section describes chip global nets, quadrant global nets, local clock nets, a list of nets listed by fanout, and net candidates for local clock assignment. Review this information. Note that YB or YC are counted as global only when they are used in isolation; if you use YB only and not GLB, this net is not shown in the global/quadrant nets report. Instead, it appears in the Global Utilization report.
2. If some signals have a very high fanout and are candidates for global promotion, promote those signals to global using the compile options or PDC commands. [Figure 3-12 on page 3-17](#) shows the Globals Management section of the compile options. Select **Promote regular nets whose fanout is greater than** and enter a reasonable value for fanouts.

Figure 3-12 • Globals Management GUI in Designer

3. Occasionally, the synthesis tool assigns a global macro to clock nets, even though the fanout is significantly less than other asynchronous signals. Select **Demote global nets whose fanout is less than** and enter a reasonable value for fanouts. This frees up some global networks from the signals that have very low fanouts. This can also be done using PDC.
4. Use local clocks for the signals that do not need to go to the whole chip but should have low skew. This local clocks assignment can only be done using PDC.
5. Assign the I/O buffer using MVN if you have fixed I/O assignment. As shown in [Figure 3-7 on page 3-9](#), there are three sets of global pins that have a hardwired connection to each global network. Do not try to put multiple CLKBUF macros in these three sets of global pins. For example, do not assign two CLKBUFs to GAA0x and GAA2x pins.
6. You must click **Commit** at the end of MVN assignment. This runs the pre-layout checker and checks the validity of global assignment.
7. Always run Compile with the **Keep existing physical constraints** option on. This uses the quadrant clock network assignment in the MVN assignment and checks if you have the desired signals on the global networks.
8. Run Layout and check the timing.

Simple Design Example

Consider a design consisting of six building blocks (shift registers) and targeted for an A3PE600-PQ208 (Figure 3-10 on page 3-15). The example design consists of two PLLs (PLL1 has GLA only; PLL2 has both GLA and GLB), a global reset (ACLR), an enable (EN_ALL), and three external clock domains (QCLK1, QCLK2, and QCLK3) driving the different blocks of the design. Note that the PQ208 package only has two PLLs (which access the chip global network). Because of fanout, the global reset and enable signals need to be assigned to the chip global resources. There is only one free chip global for the remaining global (QCLK1, QCLK2, QCLK3). Place two of these signals on the quadrant global resource. The design example demonstrates manually assignment of QCLK1 and QCLK2 to the quadrant global using the PDC command.

Figure 3-13 • Block Diagram of the Global Management Example Design

Step 1

Run Synthesis with default options. The Synplicity log shows the following device utilization:

Cell usage:

	cell count	area	count*area
DFN1E1C1	1536	2.0	3072.0
BUFF	278	1.0	278.0
INBUF	10	0.0	0.0
VCC	9	0.0	0.0
GND	9	0.0	0.0
OUTBUF	6	0.0	0.0
CLKBUF	3	0.0	0.0
PLL	2	0.0	0.0
TOTAL	1853		3350.0

Step 2

Run Compile with the **Promote regular nets whose fanout is greater than** option selected in Designer; you will see the following in the Compile report:

Device utilization report:

```
=====
CORE                Used:   1536 Total: 13824 (11.11%)
IO (W/ clocks)     Used:    19 Total:  147 (12.93%)
Differential IO    Used:     0 Total:   65 (0.00%)
GLOBAL             Used:     8 Total:   18 (44.44%)
PLL                Used:     2 Total:    2 (100.00%)
RAM/FIFO           Used:     0 Total:   24 (0.00%)
FlashROM           Used:     0 Total:    1 (0.00%)
.....
```

The following nets have been assigned to a global resource:

```
Fanout  Type      Name
-----
1536    INT_NET      Net  : EN_ALL_c
                Driver: EN_ALL_pad_CLKINT
                Source: AUTO PROMOTED
1536    SET/RESET_NET Net  : ACLR_c
                Driver: ACLR_pad_CLKINT
                Source: AUTO PROMOTED
256     CLK_NET      Net  : QCLK1_c
                Driver: QCLK1_pad_CLKINT
                Source: AUTO PROMOTED
256     CLK_NET      Net  : QCLK2_c
                Driver: QCLK2_pad_CLKINT
                Source: AUTO PROMOTED
256     CLK_NET      Net  : QCLK3_c
                Driver: QCLK3_pad_CLKINT
                Source: AUTO PROMOTED
256     CLK_NET      Net  : $1N14
                Driver: $1I5/Core
                Source: ESSENTIAL
256     CLK_NET      Net  : $1N12
                Driver: $1I6/Core
                Source: ESSENTIAL
256     CLK_NET      Net  : $1N10
                Driver: $1I6/Core
                Source: ESSENTIAL
```

Designer will promote five more signals to global due to high fanout. There are eight signals assigned to global networks.

During Layout, Designer will assign two of the signals to quadrant global locations.

Step 3 (optional)

You can also assign the QCLK1_c and QCLK2_c nets to quadrant regions using the following PDC commands:

```
assign_local_clock -net QCLK1_c -type quadrant UL
assign_local_clock -net QCLK2_c -type quadrant LL
```

Step 4

Import this PDC with the netlist and run Compile again. You will see the following in the Compile report:

The following nets have been assigned to a global resource:

Fanout	Type	Name
1536	INT_NET	Net : EN_ALL_c Driver: EN_ALL_pad_CLKINT Source: AUTO PROMOTED
1536	SET/RESET_NET	Net : ACLR_c Driver: ACLR_pad_CLKINT Source: AUTO PROMOTED
256	CLK_NET	Net : QCLK3_c Driver: QCLK3_pad_CLKINT Source: AUTO PROMOTED
256	CLK_NET	Net : \$1N14 Driver: \$1I5/Core Source: ESSENTIAL
256	CLK_NET	Net : \$1N12 Driver: \$1I6/Core Source: ESSENTIAL
256	CLK_NET	Net : \$1N10 Driver: \$1I6/Core Source: ESSENTIAL

The following nets have been assigned to a quadrant clock resource using PDC:

Fanout	Type	Name
256	CLK_NET	Net : QCLK1_c Driver: QCLK1_pad_CLKINT Region: quadrant_UL
256	CLK_NET	Net : QCLK2_c Driver: QCLK2_pad_CLKINT Region: quadrant_LL

Step 5

Run Layout.

Global Management in PLL Design

This section describes the legal global network connections to PLLs in the low-power flash devices. For detailed information on using PLLs, refer to *Clock Conditioning Circuits in IGLOO and ProASIC3 Devices*. Actel recommends that you use the dedicated global pins to directly drive the reference clock input of the associated PLL for reduced propagation delays and clock distortion. However, low-power flash devices offer the flexibility to connect other signals to reference clock inputs. Each PLL is associated with three global networks (Figure 3-8 on page 3-10). There are some limitations, such as when trying to use the global and PLL at the same time:

- If you use a PLL with only primary output, you can still use the remaining two free global networks.
- If you use three globals associated with a PLL location, you cannot use the PLL on that location.
- If the YB or YC output is used standalone, it will occupy one global, even though this signal does not go to the global network.

Using Spines of Occupied Global Networks

When a signal is assigned to a global network, the flash switches are programmed to set the MUX select lines (explained in the "Clock Aggregation Architecture" section on page 3-9) to drive the spines of that network with the global net. However, if the global net is restricted from reaching into the scope of a spine, the MUX drivers of that spine are available for other high-fanout or critical signals (Figure 3-14).

For example, if you want to limit the CLK1_c signal to the left half of the chip and want to use the right side of the same global network for CLK2_c, you can add the following PDC commands:

```
define_region -name region1 -type inclusive 0 0 34 29
assign_net_macros region1 CLK1_c
assign_local_clock -net CLK2_c -type chip B2
```

Figure 3-14 • Design Example Using Spines of Occupied Global Networks

Conclusion

IGLOO, Fusion, and ProASIC3 devices contain 18 global networks: 6 chip global networks and 12 quadrant global networks. These global networks can be segmented into local low-skew networks called spines. The spines provide low-skew networks for the high-fanout signals of a design. These allow you up to 252 different internal/external clocks in an A3PE3000 device. This document describes the architecture for the global network, plus guidelines and methodologies in assigning signals to globals and spines.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

Part Number 51700094-005-4

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	The "Global Architecture" section was updated to include 10 k devices, and to include information about VersaNet global support for IGLOO nano devices.	3-1
	The Table 3-1 · Flash-Based FPGAs was updated to include IGLOO nano and ProASIC3 nano devices.	3-2
	The "VersaNet Global Network Distribution" section was updated to include 10 k devices and to note an exception in global lines for nano devices.	3-3
	Figure 3-2 · Simplified VersaNet Global Network (30 k gates and below) is new.	3-4
	The "Spine Architecture" section was updated to clarify support for 10 k and nano devices.	3-5
	Table 3-2 · Globals/Spines/Rows for IGLOO and ProASIC3 Devices was updated to include IGLOO nano and ProASIC3 nano devices.	3-6
	The figure in the CLKBUF_LVDS/LVPECL row of Table 3-6 · Clock Macros was updated to change CLKBIBUF to CLKBUF.	3-12
v1.2 (June 2008)	A third bullet was added to the beginning of the "Global Architecture" section: In Fusion devices, the west CCC also contains a PLL core. In the two larger devices (AFS600 and AFS1500), the west and east CCCs each contain a PLL.	3-1
	The "Global Resource Support in Flash-Based Devices" section was revised to include new families and make the information more concise.	3-2
	Table 3-2 · Globals/Spines/Rows for IGLOO and ProASIC3 Devices was updated to include A3PE600/L in the device column.	3-6
	Table note 1 was revised in Table 3-7 · I/O Standards within CLKBUF to include AFS600 and AFS1500.	3-12
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 3-1 · Flash-Based FPGAs: <ul style="list-style-type: none"> ProASIC3L was updated to include 1.5 V. The number of PLLs for ProASIC3E was changed from five to six. 	3-2
v1.0 (January 2008)	The "Global Architecture" section was updated to include the IGLOO PLUS family. The bullet was revised to include that the west CCC does not contain a PLL core in 15 k and 30 k devices. Instances of "A3P030 and AGL030 devices" were replaced with "15 k and 30 k gate devices."	3-1
	Table 3-1 · Flash-Based FPGAs and the accompanying text was updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "ProASIC3 Terminology" section are new.	3-2
	The "VersaNet Global Network Distribution" section, "Spine Architecture" section, the note in Figure 3-1 · Overview of VersaNet Global Network and Device Architecture, and the note in Figure 3-3 · Simplified VersaNet Global Network (60 k gates and above) were updated to include mention of 15 k gate devices.	3-3, 3-4

Previous Version	Changes in Current Version (v1.4)	Page
v1.0 (continued)	Table 3-2 · Globals/Spines/Rows for IGLOO and ProASIC3 Devices was updated to add the A3P015 device, and to revise the values for clock trees, globals/spines per tree, and globals/spines per device for the A3P030 and AGL030 devices.	3-6
	Table 3-3 · Globals/Spines/Rows for IGLOO PLUS Devices is new.	3-6
	CLKBUF_LVCMOS12 was added to Table 3-7 · I/O Standards within CLKBUF.	3-12
	The "Handbook Documents" section was updated to include the three different I/O Structures chapters for ProASIC3 and IGLOO device families.	3-22
51900087-1/3.05	Figure 3-3 · Simplified VersaNet Global Network (60 k gates and above) was updated.	3-4
	The "Naming of Global I/Os" section was updated.	3-10
	The "Using Global Macros in Synplicity" section was updated.	3-13
	The "Global Promotion and Demotion Using PDC" section was updated.	3-14
	The "Designer Flow for Global Assignment" section was updated.	3-16
	The "Simple Design Example" section was updated.	3-18

4 – Clock Conditioning Circuits in Low-Power Flash Devices and Mixed-Signal FPGAs

Introduction

This document outlines the following device information: Clock Conditioning Circuit (CCC) features, PLL core specifications, functional descriptions, software configuration information, detailed usage information, recommended board-level considerations, and other considerations concerning clock conditioning circuits and global networks in low-power flash devices or mixed-signal FPGAs.

Overview of Clock Conditioning Circuitry

In Fusion, IGLOO®, and ProASIC®3 devices, the CCCs are used to implement frequency division, frequency multiplication, phase shifting, and delay operations. The CCCs are available in six chip locations—each of the four chip corners and the middle of the east and west chip sides. For device-specific variations, refer to the "Device-Specific Layout" section on page 4-17.

The CCC is composed of the following:

- PLL core
- 3 phase selectors
- 6 programmable delays and 1 fixed delay that advances/delays phase
- 5 programmable frequency dividers that provide frequency multiplication/division (not shown in Figure 4-5 on page 4-10 because they are automatically configured based on the user's required frequencies)
- 1 dynamic shift register that provides CCC dynamic reconfiguration capability

Figure 4-1 provides a simplified block diagram of the physical implementation of the building blocks in each of the CCCs.

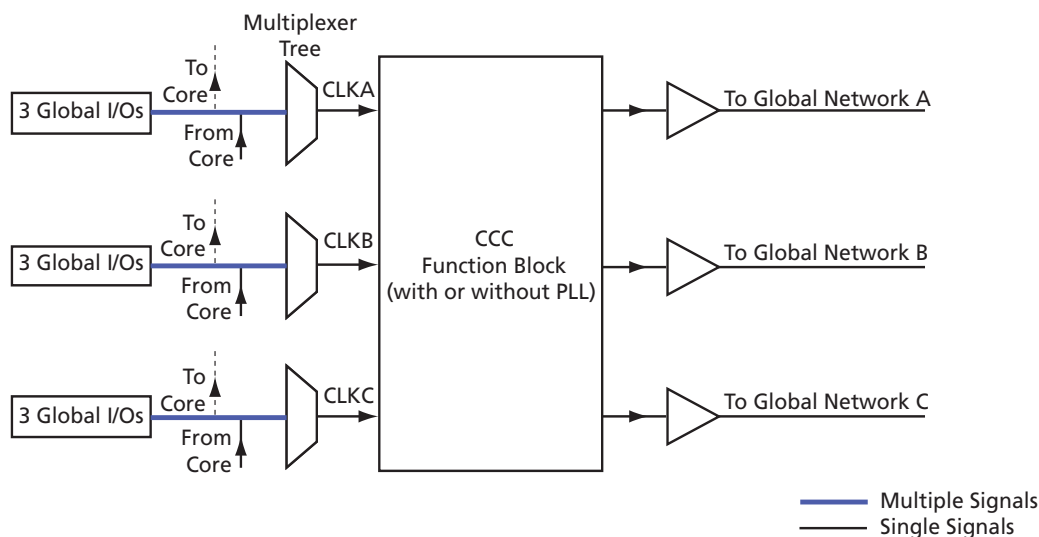

Figure 4-1 • Overview of the CCCs Offered in Fusion, IGLOO, and ProASIC3

Each CCC can implement up to three independent global buffers (with or without programmable delay) or a PLL function (programmable frequency division/multiplication, phase shift, and delays) with up to three global outputs. Unused global outputs of a PLL can be used to implement independent global buffers, up to a maximum of three global outputs for a given CCC.

CCC Programming

The CCC block is fully configurable, either via flash configuration bits set in the programming bitstream or through an asynchronous interface. This asynchronous dedicated shift register interface is dynamically accessible from inside the low-power flash devices to permit parameter changes, such as PLL divide ratios and delays, during device operation.

To increase the versatility and flexibility of the clock conditioning system, the CCC configuration is determined either by the user during the design process, with configuration data being stored in flash memory as part of the device programming procedure, or by writing data into a dedicated shift register during normal device operation.

This latter mode allows the user to dynamically reconfigure the CCC without the need for core programming. The shift register is accessed through a simple serial interface. Refer to [UJTAG Applications in Actel's Low-Power Flash Devices](#) or the application note [Using Global Resources in Actel Fusion Devices](#).

Global Resources

Low-power flash and mixed-signal devices provide three global routing networks (GLA, GLB, and GLC) for each of the CCC locations. There are potentially many I/O locations; each global I/O location can be chosen from only one of three possibilities. This is controlled by the multiplexer tree circuitry in each global network. Once the I/O location is selected, the user has the option to utilize the CCCs before the signals are connected to the global networks. The CCC in each location (up to six) has the same structure, so generating the CCC macros is always done with an identical software GUI. The CCCs in the corner locations drive the quadrant global networks, and the CCCs in the middle of the east and west chip sides drive the chip global networks. The quadrant global networks span only a quarter of the device, while the chip global networks span the entire device. For more details on global resources offered in low-power flash devices, refer to [Global Resources in Actel Low-Power Flash Devices](#).

A global buffer can be placed in any of the three global locations (CLKA-GLA, CLKB-GLB, or CLKC-GLC) of a given CCC. A PLL macro uses the CLKA CCC input to drive its reference clock. It uses the GLA and, optionally, the GLB and GLC global outputs to drive the global networks. A PLL macro can also drive the YB and YC regular core outputs. The GLB (or GLC) global output cannot be reused if the YB (or YC) output is used. Refer to the ["PLL Macro Signal Descriptions"](#) section on [page 4-8](#) for more information.

Each global buffer, as well as the PLL reference clock, can be driven from one of the following:

- 3 dedicated single-ended I/Os using a hardwired connection
- 2 dedicated differential I/Os using a hardwired connection
- The FPGA core

CCC Support in Actel's Flash Devices

The flash FPGAs listed in [Table 4-1](#) support the CCC feature and the functions described in this document.

Table 4-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
	IGLOO nano	The industry's lowest-power, smallest-size solution
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 4-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 4-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Global Buffers with No Programmable Delays

Access to the global / quadrant global networks can be configured directly from the global I/O buffer, bypassing the CCC functional block (as indicated by the dotted lines in [Figure 4-1 on page 4-1](#)). Internal signals driven by the FPGA core can use the global / quadrant global networks by connecting via the routed clock input of the multiplexer tree.

There are many specific CLKBUF macros supporting the wide variety of single-ended I/O inputs (CLKBUF) and differential I/O standards (CLKBUF_LVDS/LVPECL) in the low-power flash families. They are used when connecting global I/Os directly to the global/quadrant networks.

When an internal signal needs to be connected to the global/quadrant network, the CLKINT macro is used to connect the signal to the routed clock input of the network's MUX tree.

To utilize direct connection from global I/Os or from internal signals to the global/quadrant networks, CLKBUF, CLKBUF_LVPECL/LVDS, and CLKINT macros are used ([Figure 4-2](#)).

- The CLKBUF and CLKBUF_LVPECL/LVDS¹ macros are composite macros that include an I/O macro driving a global buffer, which uses a hardwired connection.
- The CLKBUF, CLKBUF_LVPECL/LVDS¹ and CLKINT macros are pass-through clock sources and do not use the PLL or provide any programmable delay functionality.
- The CLKINT macro provides a global buffer function driven internally by the FPGA core.

The available CLKBUF macros are described in the *IGLOO, Fusion, and ProASIC3 Macro Library Guide*.

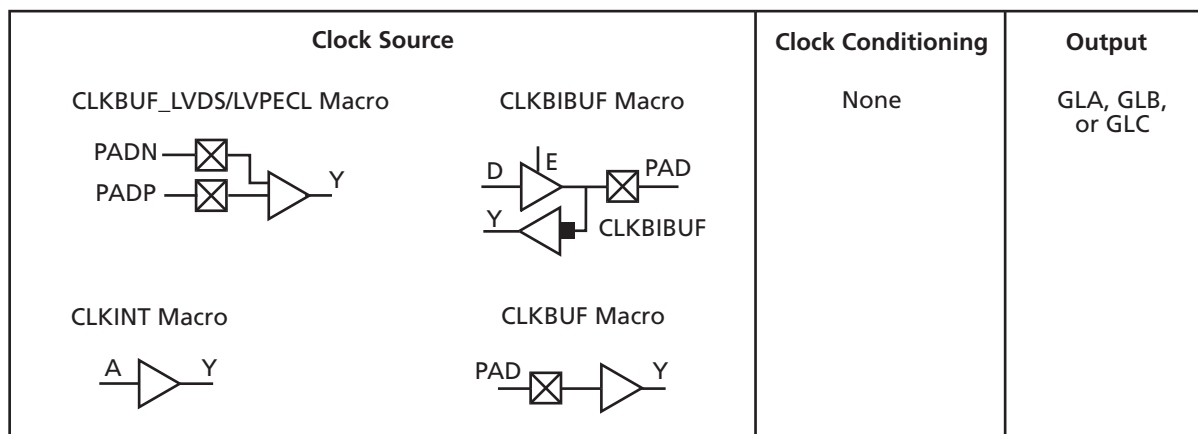

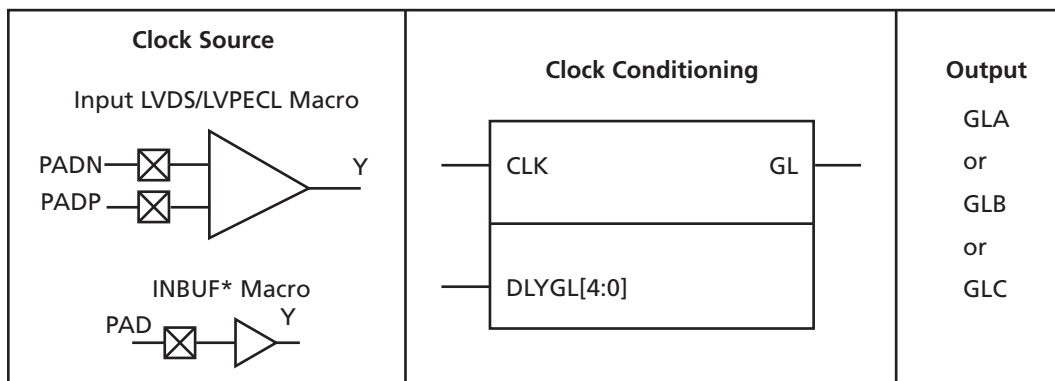

Figure 4-2 • CCC Options: Global Buffers with No Programmable Delay

Global Buffer with Programmable Delay

Clocks requiring clock adjustments can utilize the programmable delay cores before connecting to the global / quadrant global networks. A maximum of 18 CCC global buffers can be instantiated in a device—three per CCC and up to six CCCs per device.

Each CCC functional block contains a programmable delay element for each of the global networks (up to three), and users can utilize these features by using the corresponding macro ([Figure 4-3 on page 4-5](#)).

1. B-LVDS and M-LVDS are supported with the LVDS macro.

Note: For INBUF* driving a PLL macro or CLKDLY macro, the I/O will be hard-routed to the CCC; i.e., will be placed by software to a dedicated Global I/O.

Figure 4-3 • CCC Options: Global Buffers with Programmable Delay

The CLKDLY macro is a pass-through clock source that does not use the PLL, but provides the ability to delay the clock input using a programmable delay. The CLKDLY macro takes the selected clock input and adds a user-defined delay element. This macro generates an output clock phase shift from the input clock.

The CLKDLY macro can be driven by an INBUF* macro to create a composite macro, where the I/O macro drives the global buffer (with programmable delay) using a hardwired connection. In this case, the software will automatically place the dedicated global I/O in the appropriate locations. Many specific INBUF macros support the wide variety of single-ended and differential I/O standards supported by the low-power flash family. The available INBUF macros are described in the *IGLOO, Fusion, and ProASIC3 Macro Library Guide*.

The CLKDLY macro can be driven directly from the FPGA core. The CLKDLY macro can also be driven from an I/O that is routed through the FPGA regular routing fabric. In this case, users must instantiate a special macro, PLLINT, to differentiate the clock input driven by the hardwired I/O connection.

The visual CLKDLY configuration in the SmartGen area of the Actel Libero® Integrated Design Environment (IDE) and Designer tools allows the user to select the desired amount of delay and configures the delay elements appropriately. SmartGen also allows the user to select the input clock source. SmartGen will automatically instantiate the special macro, PLLINT, when needed.

CLKDLY Macro Signal Descriptions

The CLKDLY macro supports one input and one output. Each signal is described in [Table 4-2](#).

Table 4-2 • Input and Output Description of the CLKDLY Macro

Signal	Name	I/O	Description
CLK	Reference Clock	Input	Reference clock input
GL	Global Output	Output	Primary output clock to respective global/quadrant clock networks

CLKDLY Macro Usage

When a CLKDLY macro is used in a CCC location, the programmable delay element is used to allow the clock delays to go to the global network. In addition, the user can bypass the PLL in a CCC location integrated with a PLL, but use the programmable delay that is associated with the global network by instantiating the CLKDLY macro. The same is true when using programmable delay elements in a CCC location with no PLLs (the user needs to instantiate the CLKDLY macro). There is no difference between the programmable delay elements used for the PLL and the CLKDLY macro. The CCC will be configured to use the programmable delay elements in accordance with the macro instantiated by the user.

As an example, if the PLL is not used in a particular CCC location, the designer is free to specify up to three CLKDLY macros in the CCC, each of which can have its own input frequency and delay adjustment options. If the PLL core is used, assuming output to only one global clock network, the other two global clock networks are free to be used by either connecting directly from the global inputs or connecting from one or two CLKDLY macros for programmable delay.

The programmable delay elements are shown in the block diagram of the PLL block shown in [Figure 4-5 on page 4-10](#). Note that any CCC locations with no PLL present contain only the programmable delay blocks going to the global networks (labeled "Programmable Delay Type 2"). Refer to the "[Clock Delay Adjustment](#)" section on [page 4-25](#) for a description of the programmable delay types used for the PLL. Also refer to [Table 4-13 on page 4-31](#) for Programmable Delay Type 1 step delay values, and [Table 4-14 on page 4-32](#) for Programmable Delay Type 2 step delay values. CCC locations with a PLL present can be configured to utilize only the programmable delay blocks (Programmable Delay Type 2) going to the global networks A, B, and C.

Global network A can be configured to use only the programmable delay element (bypassing the PLL) if the PLL is not used in the design. [Figure 4-5 on page 4-10](#) shows a block diagram of the PLL, where the programmable delay elements are used for the global networks (Programmable Delay Type 2).

Global Buffers with PLL Function

Clocks requiring frequency synthesis or clock adjustments can utilize the PLL core before connecting to the global / quadrant global networks. A maximum of 18 CCC global buffers can be instantiated in a device—three per CCC and up to six CCCs per device. Each PLL core can generate up to three global/quadrant clocks, while a clock delay element provides one.

The PLL functionality of the clock conditioning block is supported by the PLL macro.

Notes:

1. For Fusion only.
2. Refer to the *IGLOO, Fusion, and ProASIC3 Macro Library Guide* for more information.
3. For INBUF* driving a PLL macro or CLKDLY macro, the I/O will be hard-routed to the CCC; i.e., will be placed by software to a dedicated Global I/O.

Figure 4-4 • CCC Options: Global Buffers with PLL

The PLL macro provides five derived clocks (three independent) from a single reference clock. The PLL macro also provides power-down input and lock output signals. The additional inputs shown on the macro are configuration settings, which are configured through the use of SmartGen. For manual setting of these bits refer to the *IGLOO, Fusion, and ProASIC3 Macro Library Guide* for details.

Figure 4-5 on page 4-10 illustrates the various clock output options and delay elements.

PLL Macro Signal Descriptions

The PLL macro supports two inputs and up to six outputs. [Table 4-3](#) gives a description of each signal.

Table 4-3 • Input and Output Signals of the PLL Block

Signal	Name	I/O	Description
CLKA	Reference Clock	Input	Reference clock input for PLL core; input clock for primary output clock, GLA
OADIVRST	Reset Signal for the Output Divider A	Input	For Fusion only. OADIVRST can be used when you bypass the PLL core (i.e., OAMUX = 001). The purpose of the OADIVRST signals is to reset the output of the final clock divider to synchronize it with the input to that divider when the PLL is bypassed. The signal is active on a low to high transition. The signal must be low for at least one divider input. If PLL core is used, this signal is "don't care" and the internal circuitry will generate the reset signal for the synchronization purpose.
OADIVHALF	Output A Division by Half	Input	For Fusion only. Active high. Division by half feature. This feature can only be used when users bypass the PLL core (i.e., OAMUX = 001) and the RC Oscillator (RCOSC) drives the CLKA input. This can be used to divide the 100 MHz RC oscillator by a factor of 1.5, 2.5, 3.5, 4.5 ... 14.5). Refer to Table 4-17 on page 4-33 for more information.
EXTFB	External Feedback	Input	Allows an external signal to be compared to a reference clock in the PLL core's phase detector.
POWERDOWN	Power Down	Input	Active low input that selects power-down mode and disables the PLL. With the POWERDOWN signal asserted, the PLL core sends 0 V signals on all of the outputs.
GLA	Primary Output	Output	Primary output clock to respective global/quadrant clock networks
GLB	Secondary 1 Output	Output	Secondary 1 output clock to respective global/quadrant clock networks
YB	Core 1 Output	Output	Core 1 output clock to local routing network
GLC	Secondary 2 Output	Output	Secondary 2 output clock to respective global/quadrant clock networks
YC	Core 2 Output	Output	Core 2 output clock to local routing network
LOCK	PLL Lock Indicator	Output	Active high signal indicating that steady-state lock has been achieved between CLKA and the PLL feedback signal

Input Clock

The inputs to the input reference clock (CLKA) of the PLL can come from global input pins, regular I/O pins, or internally from the core. For Fusion families, the input reference clock can also be from the embedded RC oscillator or crystal oscillator.

Global Output Clocks

GLA (Primary), GLB (Secondary 1), and GLC (Secondary 2) are the outputs of Global Multiplexer 1, Global Multiplexer 2, and Global Multiplexer 3, respectively. These signals (GLx) can be used to drive the high-speed global and quadrant networks of the low-power flash devices.

A global multiplexer block consists of the input routing for selecting the input signal for the GLx clock and the output multiplexer, as well as delay elements associated with that clock.

Core Output Clocks

YB and YC are known as Core Outputs and can be used to drive internal logic without using global network resources. This is especially helpful when global network resources must be conserved and utilized for other timing-critical paths.

YB and YC are identical to GLB and GLC, respectively, with the exception of a higher selectable final output delay. The SmartGen PLL Wizard will configure these outputs according to user specifications and can enable these signals with or without the enabling of Global Output Clocks. The above signals can be enabled in the following output groupings in both internal and external feedback configurations of the static PLL:

- One output – GLA only
- Two outputs – GLA + (GLB and/or YB)
- Three outputs – GLA + (GLB and/or YB) + (GLC and/or YC)

PLL Macro Block Diagram

As illustrated, the PLL supports three distinct output frequencies from a given input clock. Two of these (GLB and GLC) can be routed to the B and C global network access, respectively, and/or routed to the device core (YB and YC).

There are five delay elements to support phase control on all five outputs (GLA, GLB, GLC, YB, and YC).

There are delay elements in the feedback loop that can be used to advance the clock relative to the reference clock.

The PLL macro reference clock can be driven in the following ways:

1. By an INBUF* macro to create a composite macro, where the I/O macro drives the global buffer (with programmable delay) using a hardwired connection. In this case, the I/O must be placed in one of the dedicated global I/O locations.
2. Directly from the FPGA core.
3. From an I/O that is routed through the FPGA regular routing fabric. In this case, users must instantiate a special macro, PLLINT, to differentiate from the hardwired I/O connection described earlier.

During power-up, the PLL outputs will toggle around the maximum frequency of the voltage-controlled oscillator (VCO) gear selected. Toggle frequencies can range from 40 MHz to 250 MHz. This will continue as long as the clock input (CLKA) is constant (HIGH or LOW). This can be prevented by LOW assertion of the POWERDOWN signal.

The visual PLL configuration in SmartGen, a component of the Libero IDE and Designer tools, will derive the necessary internal divider ratios based on the input frequency and desired output frequencies selected by the user.

SmartGen also allows the user to select the various delays and phase shift values necessary to adjust the phases between the reference clock (CLKA) and the derived clocks (GLA, GLB, GLC, YB, and YC). SmartGen allows the user to select the input clock source. SmartGen automatically instantiates the special macro, PLLINT, when needed.

Note: Clock divider and clock multiplier blocks are not shown in this figure or in SmartGen. They are automatically configured based on the user's required frequencies.

Figure 4-5 • CCC with PLL Block

Global Input Selections

Low-power flash devices provide the flexibility of choosing one of the three global input pad locations available to connect to a CCC functional block or to a global / quadrant global network. [Figure 4-6](#) and [Figure 4-7](#) on page 4-11 show the detailed architecture of each global input structure for 30 k gate devices and below, as well as 60 k gate devices and above, respectively. For 60 k gate devices and above ([Figure 4-6](#)), if the single-ended I/O standard is chosen, there is flexibility to choose one of the global input pads (the first, second, and fourth input). Once chosen, the other I/O locations are used as regular I/Os. If the differential I/O standard is chosen, the first and second inputs are considered as paired, and the third input is paired with a regular I/O.

The user then has the choice of selecting one of the two sets to be used as the clock input source to the CCC functional block. There is also the option to allow an internal clock signal to feed the global network or the CCC functional block. A multiplexer tree selects the appropriate global input for routing to the desired location. Note that the global I/O pads do not need to feed the global network; they can also be used as regular I/O pads.

Figure 4-6 • Clock Input Sources (30 k gates devices and below)

GAA[0:2]: GA represents global in the northwest corner of the device. A[0:2]: designates specific A clock source.

Notes:

1. Represents the global input pins. Globals have direct access to the clock conditioning block and are not routed via the FPGA fabric. Refer to *User I/O Naming Conventions in I/O Structures in IGL00 and ProASIC3 Devices*.
2. Instantiate the routed clock source input as follows:
 - a) Connect the output of a logic element to the clock input of a PLL, CLKDLY, or CLKINT macro.
 - b) Do not place a clock source I/O (INBUF or INBUF_LVPECL/LVDS/SIB-LVDS/M-LVDS/DDR) in a relevant global pin location.

Figure 4-7 • Clock Input Sources Including CLKBUF, CLKBUF_LVDS/LVPECL, and CLKINT (60 k gates devices and above)

Each global buffer, as well as the PLL reference clock, can be driven from one of the following:

- 3 dedicated single-ended I/Os using a hardwired connection
- 2 dedicated differential I/Os using a hardwired connection
- The FPGA core

Since the architecture of the devices varies as size increases, the following list details I/O types supported for globals:

IGLOO and ProASIC3

- LVDS-based clock sources are available only on 250 k gate devices and above.
- 60 k and 125 k gate devices support single-ended clock sources only.
- 15 k and 30 k gate devices support these inputs for CCC only and do not contain a PLL.
- nano devices:
 - 10 k, 15 k, and 20 k devices do not contain PLLs in the CCCs, and support only CLKBUF and CLKINT.
 - 60 k, 125 k, and 250 k devices support one PLL in the middle left CCC position. In the absence of the PLL, this CCC can be used by CLKBUF, CLKINT, and CLKDLY macros. The corner CCCs support CLKBUF, CLKINT, and CLKDLY.

Fusion

- AFS600 and AFS1500: All single-ended, differential, and voltage-referenced I/O standards (Pro I/O).
- AFS090 and AFS250: All single-ended and differential I/O standards.

Clock Sources for PLL and CLKDLY Macros

The input reference clock (CLKA for a PLL macro, CLK for a CLKDLY macro) can be accessed from different sources via the associated clock multiplexer tree. Each CCC has the option of choosing the source of the input clock from one of the following:

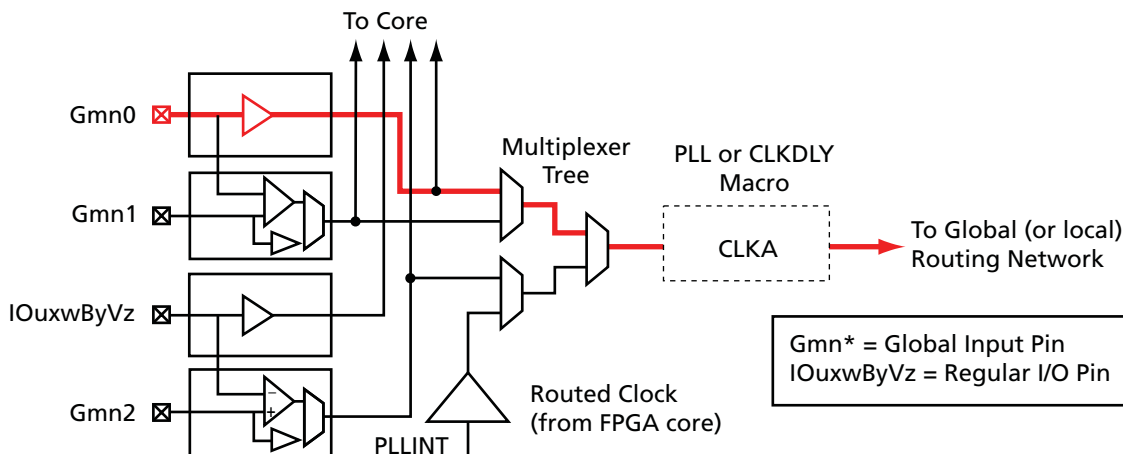

- Hardwired I/O
- External I/O
- Core Logic
- RC Oscillator (Fusion only)
- Crystal Oscillator (Fusion only)

The SmartGen macro builder tool allows users to easily create the PLL and CLKDLY macros with the desired settings. Actel strongly recommends using SmartGen to generate the CCC macros.

Hardwired I/O Clock Source

Hardwired I/O refers to global input pins that are hardwired to the multiplexer tree, which directly accesses the CCC global buffers. These global input pins have designated pin locations and are indicated with the I/O naming convention *Gmn* (*m* refers to any one of the positions where the PLL core is available, and *n* refers to any one of the three global input MUXes and the pin number of the associated global location, *m*). Choosing this option provides the benefit of directly connecting to the CCC reference clock input, which provides less delay. See [Figure 4-8 on page 4-13](#) for an example illustration of the connections, shown in red. If a CLKDLY macro is initiated to utilize the programmable delay element of the CCC, the clock input can be placed at one of nine dedicated global input pin locations. In other words, if Hardwired I/O is chosen as the input source, the user can decide to place the input pin in one of the GmA0, GmA1, GmA2, GmB0, GmB1, GmB2, GmC0, GmC1, or GmC2 locations of the low-power flash devices. When a PLL macro is used to utilize the

PLL core in a CCC location, the clock input of the PLL can only be connected to one of three GmA* global pin locations: GmA0, GmA1, or GmA2.

Note: Fusion CCCs have additional source selections (RCOSC, XTAL).

Figure 4-8 • Illustration of Hardwired I/O (global input pins) Usage for IGLOO and ProASIC3 devices 60 k Gates and Larger

Figure 4-9 • Illustration of Hardwired I/O (global input pins) Usage for IGLOO and ProASIC3 devices 30 k Gates and Smaller

External I/O Clock Source

External I/O refers to regular I/O pins. The clock source is instantiated with one of the various INBUF options and accesses the CCCs via internal routing. The user has the option of assigning this input to any of the I/Os labeled with the I/O convention *IOuxwByVz*. Refer to [User I/O Naming Conventions in I/O Structures in IGLOO and ProASIC3 Devices](#), and for Fusion, refer to the [Fusion Mixed-Signal Programmable System Chip](#) datasheet for more information. [Figure 4-10](#) gives a brief explanation of external I/O usage. Choosing this option provides the freedom of selecting any user I/O location but introduces additional delay because the signal connects to the routed clock input through internal routing before connecting to the CCC reference clock input.

For the External I/O option, the routed signal would be instantiated with a PLLINT macro before connecting to the CCC reference clock input. This instantiation is conveniently done automatically by SmartGen when this option is selected. Actel recommends using the SmartGen tool to generate the CCC macro. The instantiation of the PLLINT macro results in the use of the routed clock input of the I/O to connect to the PLL clock input. If not using SmartGen, manually instantiate a PLLINT macro before the PLL reference clock to indicate that the regular I/O driving the PLL reference clock should be used (see [Figure 4-10 on page 4-14](#) for an example illustration of the connections, shown in red).

In the above two options, the clock source must be instantiated with one of the various INBUF macros. The reference clock pins of the CCC functional block core macros must be driven by regular input macros (INBUFs), not clock input macros.

Figure 4-10 • Illustration of External I/O Usage

For Fusion devices, the input reference clock can also be from the embedded RC oscillator and crystal oscillator. In this case, the CCC configuration is the same as the hardwired I/O clock source, and users are required to instantiate the RC oscillator or crystal oscillator macro and connect its output to the input reference clock of the CCC block.

Core Logic Clock Source

Core logic refers to internal routed nets. Internal routed signals access the CCC via the FPGA Core Fabric. Similar to the External I/O option, whenever the clock source comes internally from the core itself, the routed signal is instantiated with a PLLINT macro before connecting to the CCC clock input (see Figure 4-11 for an example illustration of the connections, shown in red).

Figure 4-11 • Illustration of Core Logic Usage

For Fusion devices, the input reference clock can also be from the embedded RC oscillator and crystal oscillator. In this case, the CCC configuration is the same as the hardwired I/O clock source, and users are required to instantiate the RC oscillator or crystal oscillator macro and connect its output to the input reference clock of the CCC block.

Available I/O Standards

Notes:

1. By default, the CLKBUF macro uses 3.3 V LVTTTL I/O technology. For more details, refer to the IGLOO, Fusion, and ProASIC3 Macro Library Guide.
2. I/O standards only supported in ProASIC3E and IGLOOe families.
3. I/O standards only supported in the following Fusion devices: AFS600 and AFS1500.
4. B-LVDS and M-LVDS standards are supported by CLKBUF_LVDS.

Global Synthesis Constraints

The Synplify[®] synthesis tool, by default, allows six clocks in a design for Fusion, IGLOO, and ProASIC3. When more than six clocks are needed in the design, a user synthesis constraint attribute, `syn_global_buffers`, can be used to control the maximum number of clocks (up to 18) that can be inferred by the synthesis engine.

High-fanout nets will be inferred with clock buffers and/or internal clock buffers. If the design consists of CCC global buffers, they are included in the count of clocks in the design.

The subsections below discuss the clock input source (global buffers with no programmable delays) and the clock conditioning functional block (global buffers with programmable delays and/or PLL function) in detail.

Device-Specific Layout

Two kinds of CCCs are offered in low-power flash devices: CCCs with integrated PLLs, and CCCs without integrated PLLs (simplified CCCs). [Table 4-5](#) lists the number of CCCs in various devices.

Table 4-5 • Number of CCCs by Device Size and Package

Device		Package	CCCs with Integrated PLLs	CCCs without Integrated PLLs (simplified CCC)
ProASIC3	IGLOO

Note: nano 10 k, 15 k, and 20 k offer 6 global MUXes instead of CCCs.

This section outlines the following device information: CCC features, PLL core specifications, functional descriptions, software configuration information, detailed usage information, recommended board-level considerations, and other considerations concerning global networks in low-power flash devices.

Clock Conditioning Circuits with Integrated PLLs

Each of the CCCs with integrated PLLs includes the following:

- 1 PLL core, which consists of a phase detector, a low-pass filter, and a four-phase voltage-controlled oscillator
- 3 global multiplexer blocks that steer signals from the global pads and the PLL core onto the global networks
- 6 programmable delays and 1 fixed delay for time advance/delay adjustments
- 5 programmable frequency divider blocks to provide frequency synthesis (automatically configured by the SmartGen macro builder tool)

Clock Conditioning Circuits without Integrated PLLs

There are two types of simplified CCCs without integrated PLLs in low-power flash devices.

1. The simplified CCC with programmable delays, which is composed of the following:
 - 3 global multiplexer blocks that steer signals from the global pads and the programmable delay elements onto the global networks
 - 3 programmable delay elements to provide time delay adjustments
2. The simplified CCC (referred to as CCC-GL) without programmable delay elements, which is composed of the following:
 - A global multiplexer block that steer signals from the global pads onto the global networks

CCC Locations

CCCs located in the middle of the east and west sides of the device access the three VersaNet global networks on each side (six total networks), while the four CCCs located in the four corners access three quadrant global networks (twelve total networks). See Figure 4-12.

Figure 4-12 • Global Network Architecture for 60 k Gate Devices and Above

The following explains the locations of the CCCs in IGLOO and ProASIC3 devices:

In [Figure 4-14 on page 4-21](#) through [Figure 4-15 on page 4-21](#), CCCs with integrated PLLs are indicated in red, and simplified CCCs are indicated in yellow. There is a letter associated with each location of the CCC, in clockwise order. The upper left corner CCC is named "A," the upper right is named "B," and so on. These names finish up at the middle left with letter "F."

IGLOO and ProASIC3 CCC Locations

In all IGLOO and ProASIC3 devices (except 10 k through 30 k gate devices, which do not contain PLLs), six CCCs are located in the same positions as the IGLOOe and ProASIC3E CCCs. Only one of the CCCs has an integrated PLL and is located in the middle of the west (middle left) side of the device. The other five CCCs are simplified CCCs and are located in the four corners and the middle of the east side of the device ([Figure 4-13](#)).

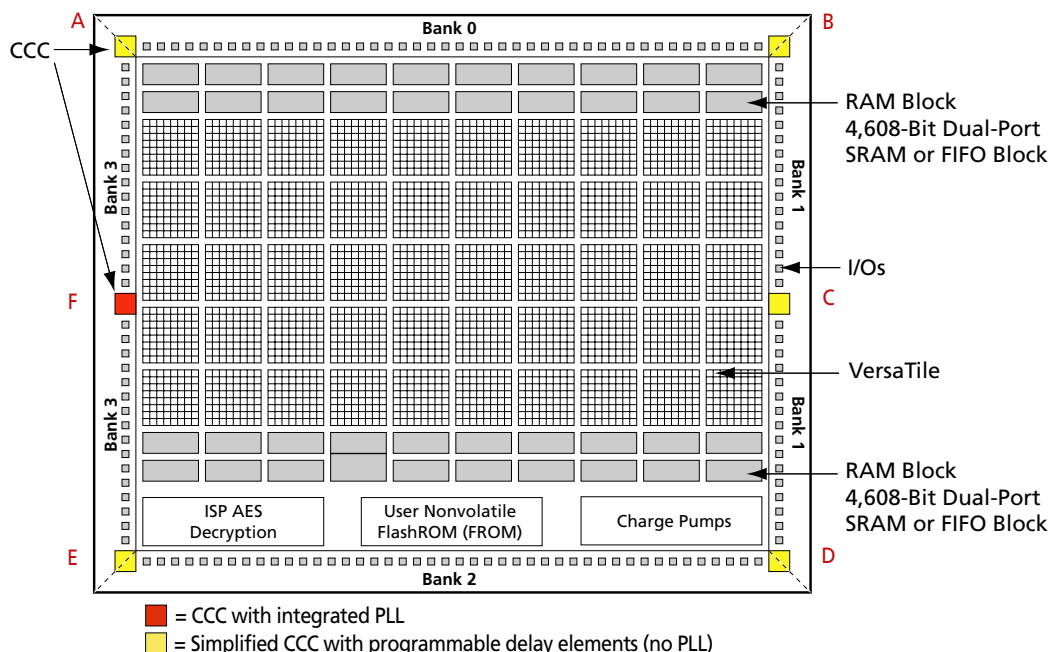

Figure 4-13 • CCC Locations in IGLOO and ProASIC3 Family Devices (except 10 k through 30 k gate devices)

Note: The number and architecture of the banks are different for some devices.

10 k through 30 k gate devices do not support PLL features. In these devices, there are two CCC-GLs at the lower corners (one at the lower right, and one at the lower left). These CCC-GLs do not have programmable delays.

IGLOOe and ProASIC3E CCC Locations

IGLOOe and ProASIC3E devices have six CCCs—one in each of the four corners and one each in the middle of the east and west sides of the device (Figure 4-14).

All six CCCs are integrated with PLLs, except in PQFP-208 package devices. PQFP-208 package devices also have six CCCs, of which two include PLLs and four are simplified CCCs. The CCCs with PLLs are implemented in the middle of the east and west sides of the device (middle right and middle left). The simplified CCCs without PLLs are located in the four corners of the device (Figure 4-15).

Figure 4-14 • CCC Locations in IGLOOe and ProASIC3E Family Devices (except PQFP-208 package)

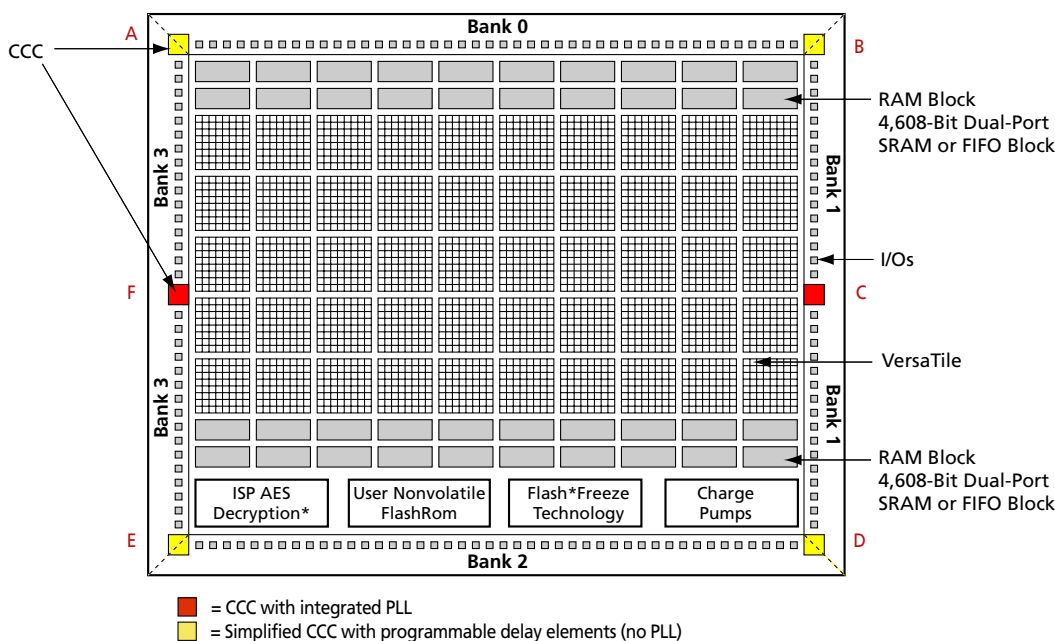

Figure 4-15 • CCC Locations in ProASIC3E Family Devices (PQFP-208 package)

Fusion CCC Locations

Fusion devices have six CCCs: one in each of the four corners and one each in the middle of the east and west sides of the device (Figure 4-16 and Figure 4-17). The device can have one integrated PLL in the middle of the west side of the device or two integrated PLLs in the middle of the east and west sides of the device (middle right and middle left).

Figure 4-16 • CCC Locations in Fusion Family Devices (AFS090, AFS250, M1AFS250)

Figure 4-17 • CCC Locations in Fusion Family Devices (except AFS090, AFS250, M1AFS250)

PLL Core Specifications

PLL core specifications can be found in the DC and Switching Characteristics chapter of the appropriate family datasheet.

Loop Bandwidth

Common design practice for systems with a low-noise input clock is to have PLLs with small loop bandwidths to reduce the effects of noise sources at the output. Table 4-6 shows the PLL loop bandwidth, providing a measure of the PLL's ability to track the input clock and jitter.

Table 4-6 • -3 dB Frequency of the PLL

	Minimum ($T_a = +125^\circ\text{C}$, $V_{CCA} = 1.4\text{ V}$)	Typical ($T_a = +25^\circ\text{C}$, $V_{CCA} = 1.5\text{ V}$)	Maximum ($T_a = -55^\circ\text{C}$, $V_{CCA} = 1.6\text{ V}$)
-3 dB Frequency	15 kHz	25 kHz	45 kHz

PLL Core Operating Principles

This section briefly describes the basic principles of PLL operation. The PLL core is composed of a phase detector (PD), a low-pass filter (LPF), and a four-phase voltage-controlled oscillator (VCO). Figure 4-18 illustrates a basic single-phase PLL core with a divider and delay in the feedback path.

Figure 4-18 • Simplified PLL Core with Feedback Divider and Delay

The PLL is an electronic servo loop that phase-aligns the PD feedback signal with the reference input. To achieve this, the PLL dynamically adjusts the VCO output signal according to the average phase difference between the input and feedback signals.

The first element is the PD, which produces a voltage proportional to the phase difference between its inputs. A simple example of a digital phase detector is an Exclusive-OR gate. The second element, the LPF, extracts the average voltage from the phase detector and applies it to the VCO. This applied voltage alters the resonant frequency of the VCO, thus adjusting its output frequency.

Consider Figure 4-18 with the feedback path bypassing the divider and delay elements. If the LPF steadily applies a voltage to the VCO such that the output frequency is identical to the input frequency, this steady-state condition is known as lock. Note that the input and output phases are also identical. The PLL core sets a LOCK output signal HIGH to indicate this condition.

Should the input frequency increase slightly, the PD detects the frequency/phase difference between its reference and feedback input signals. Since the PD output is proportional to the phase difference, the change causes the output from the LPF to increase. This voltage change increases the resonant frequency of the VCO and increases the feedback frequency as a result. The PLL dynamically adjusts in this manner until the PD senses two phase-identical signals and steady-state lock is achieved. The opposite (decreasing PD output signal) occurs when the input frequency decreases.

Now suppose the feedback divider is inserted in the feedback path. As the division factor M (shown in Figure 4-19) is increased, the average phase difference increases. The average phase difference will cause the VCO to increase its frequency until the output signal is phase-identical to the input after undergoing division. In other words, lock in both frequency and phase is achieved when the output frequency is M times the input. Thus, clock division in the feedback path results in multiplication at the output.

A similar argument can be made when the delay element is inserted into the feedback path. To achieve steady-state lock, the VCO output signal will be delayed by the input period *less* the feedback delay. For periodic signals, this is equivalent to time-advancing the output clock by the feedback delay.

Another key parameter of a PLL system is the acquisition time. Acquisition time is the amount of time it takes for the PLL to achieve lock (i.e., phase-align the feedback signal with the input reference clock). For example, suppose there is no voltage applied to the VCO, allowing it to operate at its free-running frequency. Should an input reference clock suddenly appear, a lock would be established within the maximum acquisition time.

Functional Description

This section provides detailed descriptions of PLL block functionality: clock dividers and multipliers, clock delay adjustment, phase adjustment, and dynamic PLL configuration.

Clock Dividers and Multipliers

The PLL block contains five programmable dividers. Figure 4-19 shows a simplified PLL block.

Figure 4-19 • PLL Block Diagram

Dividers n and m (the input divider and feedback divider, respectively) provide integer frequency division factors from 1 to 128. The output dividers u , v , and w provide integer division factors from 1 to 32. Frequency scaling of the reference clock CLKA is performed according to the following formulas:

$$f_{GLA} = f_{CLKA} \times m / (n \times u) - \text{GLA Primary PLL Output Clock} \quad \text{EQ 4-1}$$

$$f_{GLB} = f_{YB} = f_{CLKA} \times m / (n \times v) - \text{GLB Secondary 1 PLL Output Clock(s)} \quad \text{EQ 4-2}$$

$$f_{GLC} = f_{YC} = f_{CLKA} \times m / (n \times w) - \text{GLC Secondary 2 PLL Output Clock(s)} \quad \text{EQ 4-3}$$

SmartGen provides a user-friendly method of generating the configured PLL netlist, which includes automatically setting the division factors to achieve the closest possible match to the requested frequencies. Since the five output clocks share the n and m dividers, the achievable output frequencies are interdependent and related according to the following formula:

$$f_{GLA} = f_{GLB} \times (v / u) = f_{GLC} \times (w / u) \quad \text{EQ 4-4}$$

Clock Delay Adjustment

There are a total of seven configurable delay elements implemented in the PLL architecture.

Two of the delays are located in the feedback path, entitled System Delay and Feedback Delay. System Delay provides a fixed delay of 2 ns (typical), and Feedback Delay provides selectable delay values from 0.6 ns to 5.56 ns in 160 ps increments (typical). For PLLs, delays in the feedback path will effectively advance the output signal from the PLL core with respect to the reference clock. Thus, the System and Feedback delays generate negative delay on the output clock. Additionally, each of these delays can be independently bypassed if necessary.

The remaining five delays perform traditional time delay and are located at each of the outputs of the PLL. Besides the fixed global driver delay of 0.755 ns for each of the global networks, the global multiplexer outputs (GLA, GLB, and GLC) each feature an additional selectable delay value from 0.025 ns to 0.76 ns in the first step, and then to 5.56 ns in 160 ps increments. The additional YB and YC signals have access to a selectable delay from 0.6 ns to 5.56 ns in 160 ps increments (typical). This is the same delay value as the CLKDLY macro. It is similar to CLKDLY, which bypasses the PLL core just to take advantage of the phase adjustment option with the delay value.

The following parameters must be taken into consideration to achieve minimum delay at the outputs (GLA, GLB, GLC, YB, and YC) relative to the reference clock: routing delays from the PLL core to CCC outputs, core outputs and global network output delays, and the feedback path delay. The feedback path delay acts as a time advance of the input clock and will offset any delays introduced beyond the PLL core output. The routing delays are determined from back-annotated simulation and are configuration-dependent.

Phase Adjustment

The output from the PLL core can be phase-adjusted with respect to the reference input clock, CLKA. The user can select a 0°, 90°, 180°, or 270° phase shift independently for each of the outputs YA, GLB/YB, and GLC/YC. Note that each of these phase-adjusted signals might also undergo further frequency division and/or time adjustment via the remaining dividers and delays located at the outputs of the PLL.

Dynamic PLL Configuration

The CCCs can be configured both statically and dynamically.

In addition to the ports available in the Static CCC, the Dynamic CCC has the dynamic shift register signals that enable dynamic reconfiguration of the CCC. With the Dynamic CCC, the ports CLKB and CLKC are also exposed. All three clocks (CLKA, CLKB, and CLKC) can be configured independently.

The CCC block is fully configurable. The following two sources can act as the CCC configuration bits.

Flash Configuration Bits

The flash configuration bits are the configuration bits associated with programmed flash switches. These bits are used when the CCC is in static configuration mode. Once the device is programmed, these bits cannot be modified. They provide the default operating state of the CCC.

Dynamic Shift Register Outputs

This source does not require core reprogramming and allows core-driven dynamic CCC reconfiguration. When the dynamic register drives the configuration bits, the user-defined core circuit takes full control over SDIN, SDOUT, SCLK, SSHIFT, and SUPDATE. The configuration bits can consequently be dynamically changed through shift and update operations in the serial register interface. Access to the logic core is accomplished via the dynamic bits in the specific tiles assigned to the PLLs.

Figure 4-20 illustrates a simplified block diagram of the MUX architecture in the CCCs.

* For Fusion, bit <88:81> is also needed.

Figure 4-20 • The CCC Configuration MUX Architecture

The selection between the flash configuration bits and the bits from the configuration register is made using the MODE signal shown in Figure 4-20. If the MODE signal is logic HIGH, the dynamic shift register configuration bits are selected. There are 81 control bits to configure the different functions of the CCC.

Each group of control bits is assigned a specific location in the configuration shift register. For a list of the 81 configuration bits (C[80:0]) in the CCC and a description of each, refer to "PLL Configuration Bits Description" on page 4-28. The configuration register can be serially loaded with the new configuration data and programmed into the CCC using the following ports:

- SDIN: The configuration bits are serially loaded into a shift register through this port. The LSB of the configuration data bits should be loaded first.
- SDOUT: The shift register contents can be shifted out (LSB first) through this port using the shift operation.
- SCLK: This port should be driven by the shift clock.
- SSHIFT: The active-high shift enable signal should drive this port. The configuration data will be shifted into the shift register if this signal is HIGH. Once SSHIFT goes LOW, the data shifting will be halted.

- SUPDATE: The SUPDATE signal is used to configure the CCC with the new configuration bits when shifting is complete.

To access the configuration ports of the shift register (SDIN, SDOUT, SSHIFT, etc.), the user should instantiate the CCC macro in his design with appropriate ports. Actel recommends that users choose SmartGen to generate the CCC macros with the required ports for dynamic reconfiguration.

Users must familiarize themselves with the architecture of the CCC core and its input, output, and configuration ports to implement the desired delay and output frequency in the CCC structure. Figure 4-21 shows a model of the CCC with configurable blocks and switches.

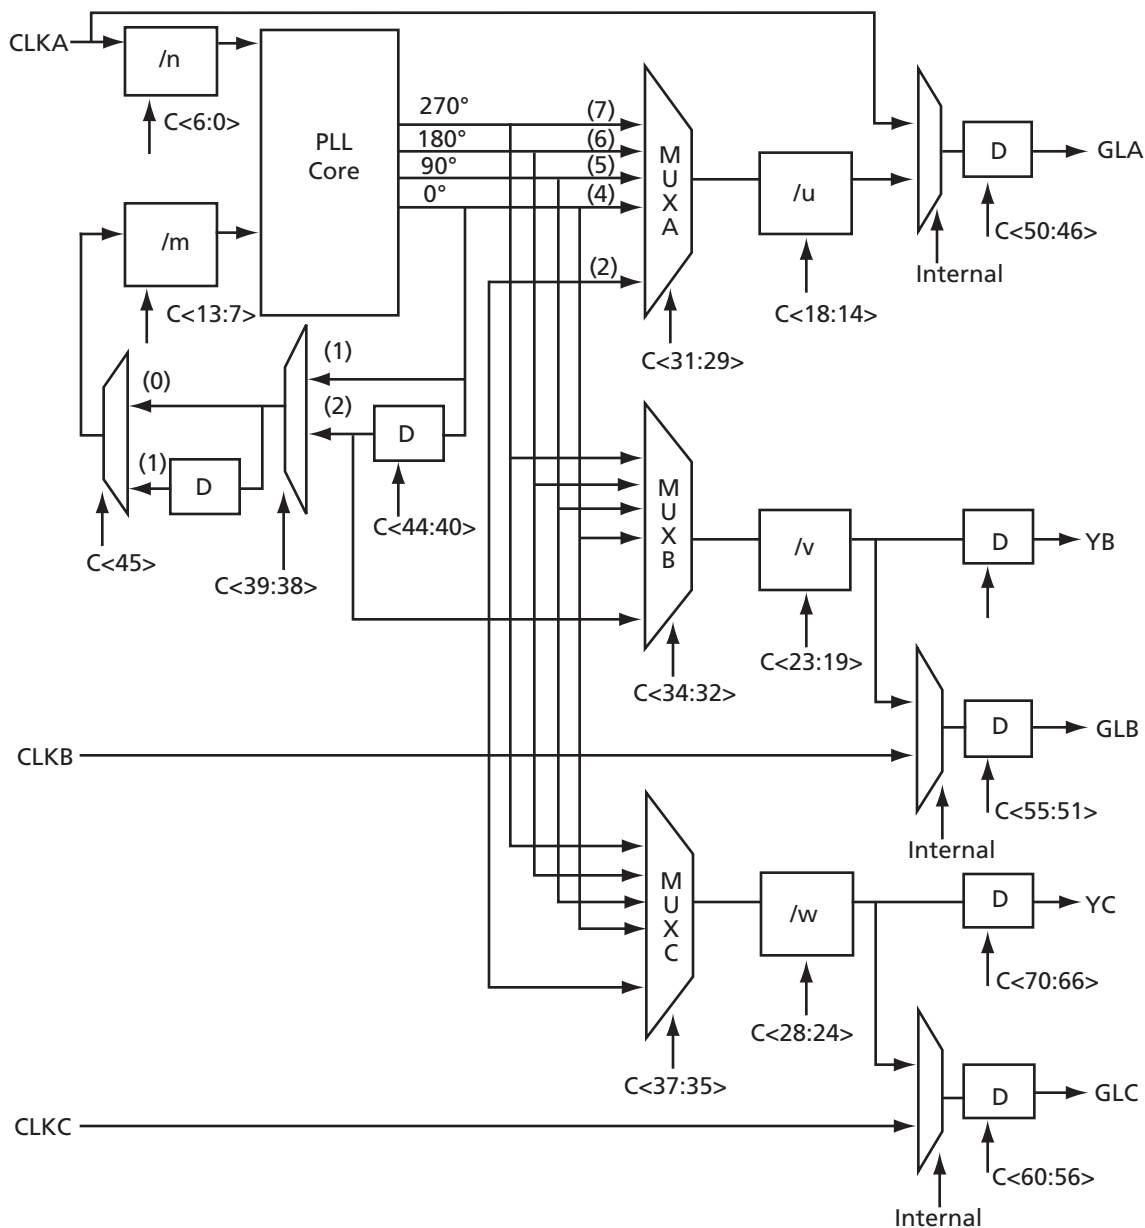

Figure 4-21 • CCC Block Control Bits – Graphical Representation of Assignments

Loading the Configuration Register

The most important part of CCC dynamic configuration is to load the shift register properly with the configuration bits. There are different ways to access and load the configuration shift register:

- JTAG interface
- Logic core
- Specific I/O tiles

JTAG Interface

The JTAG interface requires no additional I/O pins. The JTAG TAP controller is used to control the loading of the CCC configuration shift register.

Low-power flash devices provide a user interface macro between the JTAG pins and the device core logic. This macro is called UJTAG. A user should instantiate the UJTAG macro in his design to access the configuration register ports via the JTAG pins.

For more information on CCC dynamic reconfiguration using UJTAG, refer to [UJTAG Applications in Actel's Low-Power Flash Devices](#).

Logic Core

If the logic core is employed, the user must design a module to provide the configuration data and control the shifting and updating of the CCC configuration shift register. In effect, this is a user-designed TAP controller, which requires additional chip resources.

Specific I/O Tiles

If specific I/O tiles are used for configuration, the user must provide the external equivalent of a TAP controller. This does not require additional core resources but does use pins.

Shifting the Configuration Data

To enter a new configuration, all 81 bits must shift in via SDIN. After all bits are shifted, SSHIFT must go LOW and SUPDATE HIGH to enable the new configuration. For simulation purposes, bits <71:73> and <77:80> are "don't care."

The SUPDATE signal must be LOW during any clock cycle where SSHIFT is active. After SUPDATE is asserted, it must go back to the LOW state until a new update is required.

PLL Configuration Bits Description

Table 4-7 • Configuration Bit Descriptions for the CCC Blocks

Config. Bits	Signal	Name	Description
<88:87>	GLMUXCFG [1:0] ¹	NGMUX configuration	The configuration bits specify the input clocks to the NGMUX (refer to Table 4-16 on page 4-32). ²
86	OCDIVHALF ¹	Division by half	When the PLL is bypassed, the 100 MHz RC oscillator can be divided by the divider factor in Table 4-17 on page 4-33 .
85	OBDIVHALF ¹	Division by half	When the PLL is bypassed, the 100 MHz RC oscillator can be divided by a 0.5 factor (refer to Table 4-17 on page 4-33).
84	OADIVHALF ¹	Division by half	When the PLL is bypassed, the 100 MHz RC oscillator can be divided by certain 0.5 factor (refer to Table 4-15 on page 4-32).

Notes:

1. The <88:81> configuration bits are only for the Fusion dynamic CCC.
2. This value depends on the input clock source, so Layout must complete before these bits can be set. After completing Layout in Designer, generate the "CCC_Configuration" report by choosing **Tools > Report > CCC_Configuration**. The report contains the appropriate settings for these bits.

Table 4-7 • Configuration Bit Descriptions for the CCC Blocks (continued)

Config. Bits	Signal	Name	Description
83	RXCSEL ¹	CLKC input selection	Select the CLKC input clock source between RC oscillator and crystal oscillator (refer to Table 4-15 on page 4-32). ²
82	RXBSEL ¹	CLKB input selection	Select the CLKB input clock source between RC oscillator and crystal oscillator (refer to Table 4-15 on page 4-32). ²
81	RXASEL ¹	CLKA input selection	Select the CLKA input clock source between RC oscillator and crystal oscillator (refer to Table 4-15 on page 4-32). ²
80	RESETEN	Reset Enable	Enables (active high) the synchronization of PLL output dividers after dynamic reconfiguration (SUPDATE). The Reset Enable signal is READ-ONLY and should not be modified via dynamic reconfiguration.
79	DYNCSEL	Clock Input C Dynamic Select	Configures clock input C to be sent to GLC for dynamic control. ²
78	DYNBSEL	Clock Input B Dynamic Select	Configures clock input B to be sent to GLB for dynamic control. ²
77	DYNASEL	Clock Input A Dynamic Select	Configures clock input A for dynamic PLL configuration. ²
<76:74>	VCOSEL[2:0]	VCO Gear Control	Three-bit VCO Gear Control for four frequency ranges (refer to Table 4-18 on page 4-33 and Table 4-19 on page 4-33).

Table 4-19 • Configuration Bit <74> / VCOSEL<0> Selection for All Families

VCOSEL[0]	Description
0	Fast PLL lock acquisition time with high tracking jitter. Refer to the corresponding datasheet for specific value and definition.
1	Slow PLL lock acquisition time with low tracking jitter. Refer to the corresponding datasheet for specific value and definition.

Software Configuration

SmartGen automatically generates the desired CCC functional block by configuring the control bits, and allows the user to select two CCC modes: Static PLL and Delayed Clock (CLKDLY).

Static PLL Configuration

The newly implemented Visual PLL Configuration Wizard feature provides the user a quick and easy way to configure the PLL with the desired settings (Figure 4-22). The user can invoke SmartGen to set the parameters and generate the netlist file with the appropriate flash configuration bits set for the CCCs. As mentioned in "PLL Macro Block Diagram" on page 4-9, the input reference clock CLKA can be configured to be driven by Hardwired I/O, External I/O, or Core Logic. The user enters the desired settings for all the parameters (output frequency, output selection, output phase adjustment, clock delay, feedback delay, and system delay). Notice that the actual values (divider values, output frequency, delay values, and phase) are shown to aid the user in reaching the desired design frequency in real time. These values are typical-case data. Best- and worst-case data can be observed through static timing analysis in SmartTime within Designer.

For dynamic configuration, the CCC parameters are defined using either the external JTAG port or an internally defined serial interface via the built-in dynamic shift register. This feature provides the ability to compensate for changes in the external environment.

Figure 4-22 • Visual PLL Configuration Wizard

Feedback Configuration

The PLL provides both internal and external feedback delays. Depending on the configuration, various combinations of feedback delays can be achieved.

Internal Feedback Configuration

This configuration essentially sets the feedback multiplexer to route the VCO output of the PLL core as the input to the feedback of the PLL. The feedback signal can be processed with the fixed system and the adjustable feedback delay, as shown in [Figure 4-23](#). The dividers are automatically configured by SmartGen based on the user input.

Indicated below is the System Delay pull-down menu. The System Delay can be bypassed by setting it to 0. When set, it adds a 2 ns delay to the feedback path (which results in delay advancement of the output clock by 2 ns).

Figure 4-23 • Internal Feedback with Selectable System Delay

[Figure 4-24](#) shows the controllable Feedback Delay. If set properly in conjunction with the fixed System Delay, the total output delay can be advanced significantly.

Figure 4-24 • Internal Feedback with Selectable Feedback Delay

External Feedback Configuration

For certain applications, such as those requiring generation of PCB clocks that must be matched with existing board delays, it is useful to implement an external feedback, EXTFB. The Phase Detector of the PLL core will receive CLKA and EXTFB as inputs. EXTFB may be processed by the fixed System Delay element as well as the *M* divider element. The EXTFB option is currently not supported.

After setting all the required parameters, users can generate one or more PLL configurations with HDL or EDIF descriptions by clicking the **Generate** button. SmartGen gives the option of saving session results and messages in a log file:

```

The "PLL Configuration Bits Description" section on page 4-28 provides descriptions of the PLL configuration bits for completeness. The configuration bits are shown as busses only for purposes of illustration. They will actually be broken up into individual pins in compilation libraries and all simulation models. For example, the FBSEL[1:0] bus will actually appear as pins FBSEL1 and FBSEL0. The setting of these select lines for the static PLL configuration is performed by the software and is completely transparent to the user.

Dynamic PLL Configuration

To generate a dynamically reconfigurable CCC, the user should select **Dynamic CCC** in the configuration section of the SmartGen GUI (Figure 4-25). This will generate both the CCC core and the configuration shift register / control bit MUX.

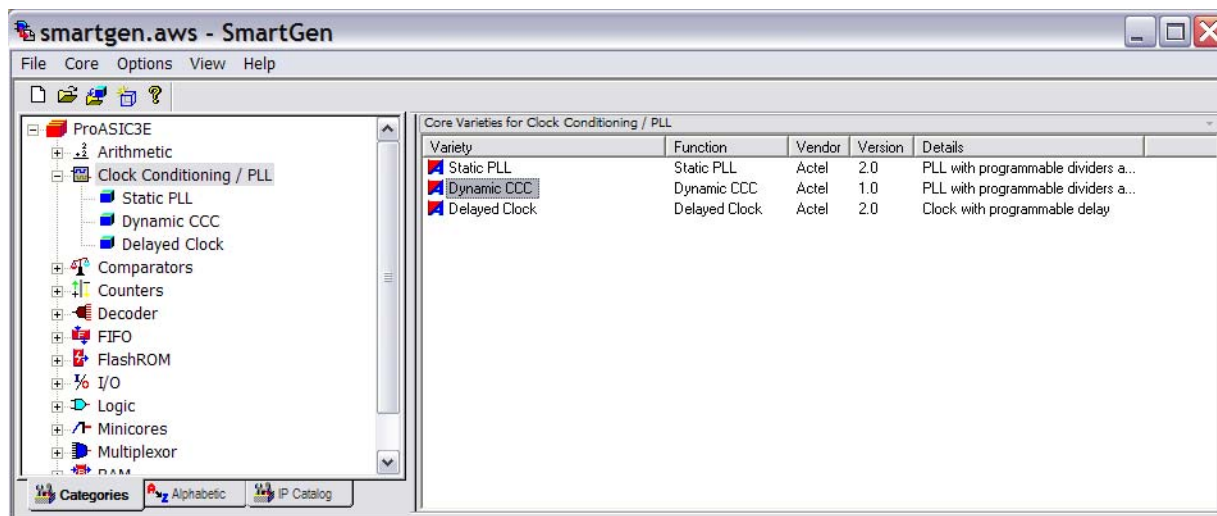

Figure 4-25 • SmartGen GUI

Even if dynamic configuration is selected in SmartGen, the user must still specify the static configuration data for the CCC (Figure 4-26). The specified static configuration is used whenever the MODE signal is set to LOW and the CCC is required to function in the static mode. The static configuration data can be used as the default behavior of the CCC where required.

Figure 4-26 • Dynamic CCC Configuration in SmartGen

When SmartGen is used to define the configuration that will be shifted in via the serial interface, SmartGen prints out the values of the 81 configuration bits. For ease of use, several configuration bits are automatically inferred by SmartGen when the dynamic PLL core is generated; however, <71:73> (STATASEL, STATBSEL, STATCSEL) and <77:79> (DYNASEL, DYNBSEL, DYNCSEL) depend on the input clock source of the corresponding CCC. Users must first run Layout in Designer to determine the exact setting for these ports. After Layout is complete, generate the "CCC_Configuration" report by choosing **Tools > Reports > CCC_Configuration** in the Designer software. Refer to "[PLL Configuration Bits Description](#)" on page 4-28 for descriptions of the PLL configuration bits. For simulation purposes, bits <71:73> and <78:80> are "don't care." Therefore, it is strongly suggested that SmartGen be used to generate the correct configuration bit settings for the dynamic PLL core.

After setting all the required parameters, users can generate one or more PLL configurations with HDL or EDIF descriptions by clicking the **Generate** button. SmartGen gives the option of saving session results and messages in a log file:

endmodule
```

Delayed Clock Configuration

The CLKDLY macro can be generated with the desired delay and input clock source (Hardwired I/O, External I/O, or Core Logic), as in Figure 4-27.

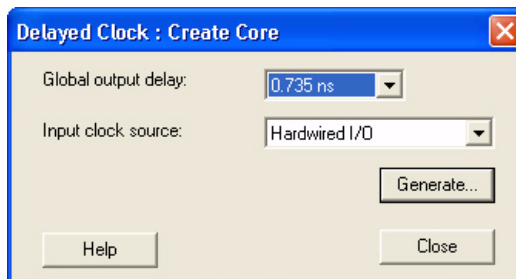

Figure 4-27 • Delayed Clock Configuration Dialog Box

After setting all the required parameters, users can generate one or more PLL configurations with HDL or EDIF descriptions by clicking the **Generate** button. SmartGen gives the option of saving session results and messages in a log file:

```
*****
Macro Parameters
*****

Name                : delay_macro
Family              : ProASIC3
Output Format        : Verilog
Type                : Delayed Clock
Delay Index         : 2
CLKA Source         : Hardwired I/O
```

Total Clock Delay = 0.935 ns.

The resultant CLKDLY macro Verilog netlist is as follows:

```
module delay_macro(GL,CLK);

output GL;
input CLK;
```

```

wire VCC, GND;

VCC VCC_1_net(.Y(VCC));
GND GND_1_net(.Y(GND));

             .DLYGL3(GND), .DLYGL4(GND));

endmodule

```

Detailed Usage Information

Clock Frequency Synthesis

Deriving clocks of various frequencies from a single reference clock is known as frequency synthesis. The PLL has an input frequency range from 1.5 to 350 MHz. This frequency is automatically divided down to a range between 1.5 MHz and 5.5 MHz by input dividers (not shown in [Figure 4-18 on page 4-23](#)) between PLL macro inputs and PLL phase detector inputs. The VCO output is capable of an output range from 24 to 350 MHz. With dividers before the input to the PLL core and following the VCO outputs, the VCO output frequency can be divided to provide the final frequency range from 0.75 to 350 MHz. Using SmartGen, the dividers are automatically set to achieve the closest possible matches to the specified output frequencies.

Users should be cautious when selecting the desired PLL input and output frequencies and the I/O buffer standard used to connect to the PLL input and output clocks. Depending on the I/O standards used for the PLL input and output clocks, the I/O frequencies have different maximum limits. Refer to the family datasheets for specifications of maximum I/O frequencies for supported I/O standards. Desired PLL input or output frequencies will not be achieved if the selected frequencies are higher than the maximum I/O frequencies allowed by the selected I/O standards. Users should be careful when selecting the I/O standards used for PLL input and output clocks. Performing post-layout simulation can help detect this type of error, which will be identified with pulse width violation errors. Users are strongly encouraged to perform post-layout simulation to ensure the I/O standard used can provide the desired PLL input or output frequencies. Users can also choose to cascade PLLs together to achieve the high frequencies needed for their applications. Details of cascading PLLs are discussed in the "[Cascading CCCs](#)" section on page 4-47.

In SmartGen, the actual generated frequency (under typical operating conditions) will be displayed beside the requested output frequency value. This provides the ability to determine the exact frequency that can be generated by SmartGen, in real time. The log file generated by SmartGen is a useful tool in determining how closely the requested clock frequencies match the user specifications. For example, assume a user specifies 101 MHz as one of the secondary output frequencies. If the best output frequency that could be achieved were 100 MHz, the log file generated by SmartGen would indicate the actual generated frequency.

Simulation Verification

The integration of the generated PLL and CLKDLY modules is similar to any VHDL component or Verilog module instantiation in a larger design; i.e., there is no special requirement that users need to take into account to successfully synthesize their designs.

For simulation purposes, users need to refer to the VITAL or Verilog library that includes the functional description and associated timing parameters. Refer to the [Software Tools](#) section of the Actel website to obtain the family simulation libraries. If Actel Designer is installed, these libraries are stored in the following locations:

```

<Designer_Installation_Directory>\lib\vt\95\proasic3.vhd
<Designer_Installation_Directory>\lib\vt\95\proasic3e.vhd
<Designer_Installation_Directory>\lib\vlog\proasic3.v
<Designer_Installation_Directory>\lib\vlog\proasic3e.v

```

For Libero IDE users, there is no need to compile the simulation libraries, as they are conveniently pre-compiled in the ModelSim® Actel simulation tool.

The following is an example of a PLL configuration utilizing the clock frequency synthesis and clock delay adjustment features. The steps include generating the PLL core with SmartGen, performing simulation for verification with ModelSim, and performing static timing analysis with SmartTime in Designer.

Parameters of the example PLL configuration:

Input Frequency – 20 MHz

Primary Output Requirement – 20 MHz with clock advancement of 3.02 ns

Secondary 1 Output Requirement – 40 MHz with clock delay of 2.515 ns

Figure 4-28 shows the SmartGen settings. Notice that the overall delays are calculated automatically, allowing the user to adjust the delay elements appropriately to obtain the desired delays.

Figure 4-28 • SmartGen Settings

After confirming the correct settings, generate a structural netlist of the PLL and verify PLL core settings by checking the log file:

```

Name                : test_pll_delays
Family              : ProASIC3E
Output Format       : VHDL
Type                : Static PLL
Input Freq(MHz)    : 20.000
CLKA Source        : Hardwired I/O
Feedback Delay Value Index : 21
Feedback Mux Select : 2
XDLY Mux Select    : No
Primary Freq(MHz)  : 20.000
Primary PhaseShift : 0
Primary Delay Value Index : 1
Primary Mux Select : 4
Secondary1 Freq(MHz) : 40.000
Use GLB            : YES
Use YB            : NO
    
```

```

...
...
...
Primary Clock frequency 20.000
Primary Clock Phase Shift 0.000
Primary Clock Output Delay from CLKA -3.020

Secondary1 Clock frequency 40.000
Secondary1 Clock Phase Shift 0.000
Secondary1 Clock Global Output Delay from CLKA 2.515

```

Next, perform simulation in ModelSim to verify the correct delays. Figure 4-29 shows the simulation results. The delay values match those reported in the SmartGen PLL Wizard.

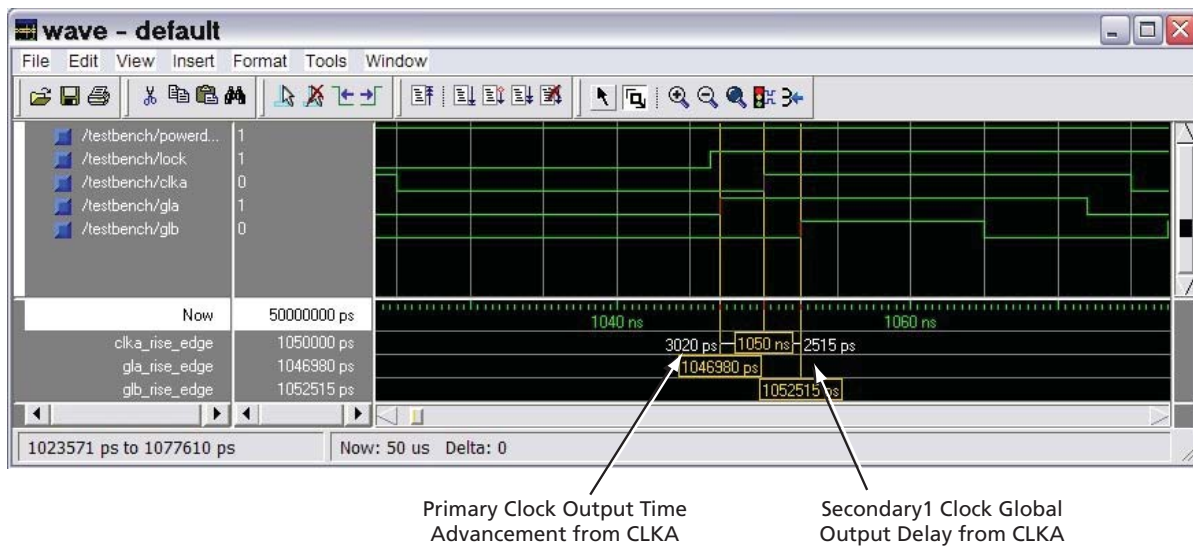

Figure 4-29 • ModelSim Simulation Results

The timing can also be analyzed using SmartTime in Designer. The user should import the synthesized netlist to Designer, perform Compile and Layout, and then invoke SmartTime. Go to **Tools > Options** and change the maximum delay operating conditions to **Typical Case**. Then expand the Clock-to-Out paths of GLA and GLB and the individual components of the path delays are shown. The path of GLA is shown in Figure 4-30 on page 4-45 displaying the same delay value.

	Pin Name	Type	Net Name	Cell Name	Op	Delay (ns)	Total (ns)	Fanout	Edge
1	From: Core:CLKA								
2	To: GLA								
3	data required time						N/C		
4	data arrival time				-		2.130		
5	slack						N/C		
6	Data arrival time calculation								
7	CLKA					0.000	0.000

16	Data required time calculation								

Figure 4-30 • Static Timing Analysis Using SmartTime

Place-and-Route Stage Considerations

Several considerations must be noted to properly place the CCC macros for layout.

For CCCs with clock inputs configured with the Hardwired I/O–Driven option:

- PLL macros must have the clock input pad coming from one of the GmA* locations.
- CLKDLY macros must have the clock input pad coming from one of the Global I/Os.

If a PLL with a Hardwired I/O input is used at a CCC location and a Hardwired I/O–Driven CLKDLY macro is used at the same CCC location, the clock input of the CLKDLY macro must be chosen from one of the GmB* or GmC* pin locations. If the PLL is not used or is an External I/O–Driven or Core Logic–Driven PLL, the clock input of the CLKDLY macro can be sourced from the GmA*, GmB*, or GmC* pin locations.

For CCCs with clock inputs configured with the External I/O–Driven option, the clock input pad can be assigned to any regular I/O location (IO***** pins). Note that since global I/O pins can also be used as regular I/Os, regardless of CCC function (CLKDLY or PLL), clock inputs can also be placed in any of these I/O locations.

By default, the Designer layout engine will place global nets in the design at one of the six chip globals. When the number of globals in the design is greater than six, the Designer layout engine will automatically assign additional globals to the quadrant global networks of the low-power flash devices. If the user wishes to decide which global signals should be assigned to chip globals (six available) and which to the quadrant globals (three per quadrant for a total of 12 available), the assignment can be achieved with PinEditor, ChipPlanner, or by importing a placement

constraint file. Layout will fail if the global assignments are not allocated properly. See the "Physical Constraints for Quadrant Clocks" section for information on assigning global signals to the quadrant clock networks.

Promoted global signals will be instantiated with CLKINT macros to drive these signals onto the global network. This is automatically done by Designer when the Auto-Promotion option is selected. If the user wishes to assign the signals to the quadrant globals instead of the default chip globals, this can be done by using ChipPlanner, by declaring a physical design constraint (PDC), or by importing a PDC file.

Physical Constraints for Quadrant Clocks

If it is necessary to promote global clocks (CLKBUF, CLKINT, PLL, CLKDLY) to quadrant clocks, the user can define PDCs to execute the promotion. PDCs can be created using PDC commands (pre-compile) or the MultiView Navigator (MVN) interface (post-compile). The advantage of using the PDC flow over the MVN flow is that the Compile stage is able to automatically promote any regular net to a global net before assigning it to a quadrant. There are three options to place a quadrant clock using PDC commands:

- Place a clock core (not hardwired to an I/O) into a quadrant clock location.
- Place a clock core (hardwired to an I/O) into an I/O location (set_io) or an I/O module location (set_location) that drives a quadrant clock location.
- Assign a net driven by a regular net or a clock net to a quadrant clock using the following command:

```
assign_local_clock -net <net name> -type quadrant <quadrant clock region>
```

where

<net name> is the name of the net assigned to the local user clock region.

<quadrant clock region> defines which quadrant the net should be assigned to. Quadrant clock regions are defined as UL (upper left), UR (upper right), LL (lower left), and LR (lower right).

Note: If the net is a regular net, the software inserts a CLKINT buffer on the net.

For example:

```
assign_local_clock -net localReset -type quadrant UR
```

Keep in mind the following when placing quadrant clocks using MultiView Navigator:

Hardwired I/O–Driven CCCs

- Find the associated clock input port under the Ports tab, and place the input port at one of the Gmn* locations using PinEditor or I/O Attribute Editor, as shown in Figure 4-31.

Figure 4-31 • Port Assignment for a CCC with Hardwired I/O Clock Input

- Use quadrant global region assignments by finding the clock net associated with the CCC macro under the Nets tab and creating a quadrant global region for the net, as shown in Figure 4-32.

Figure 4-32 • Quadrant Clock Assignment for a Global Net

External I/O–Driven CCCs

The above-mentioned recommendation for proper layout techniques will ensure the correct assignment. It is possible that, especially with External I/O–Driven CCC macros, placement of the CCC macro in a desired location may not be achieved. For example, assigning an input port of an External I/O–Driven CCC near a particular CCC location does not guarantee global assignments to the desired location. This is because the clock inputs of External I/O–Driven CCCs can be assigned to any I/O location; therefore, it is possible that the CCC connected to the clock input will be routed to a location other than the one closest to the I/O location, depending on resource availability and placement constraints.

Clock Placer

The clock placer is a placement engine for low-power flash devices that places global signals on the chip global and quadrant global networks. Based on the clock assignment constraints for the chip global and quadrant global clocks, it will try to satisfy all constraints, as well as creating quadrant clock regions when necessary. If the clock placer fails to create the quadrant clock regions for the global signals, it will report an error and stop Layout.

The user must ensure that the constraints set to promote clock signals to quadrant global networks are valid.

Cascading CCCs

The CCCs in low-power flash devices can be cascaded. Cascading CCCs can help achieve more accurate PLL output frequency results than those achievable with a single CCC. In addition, this technique is useful when the user application requires the output clock of the PLL to be a multiple of the reference clock by an integer greater than the maximum feedback divider value of the PLL (divide by 128) to achieve the desired frequency.

For example, the user application may require a 280 MHz output clock using a 2 MHz input reference clock, as shown in Figure 4-33 on page 4-48.

Figure 4-33 • Cascade PLL Configuration

Using internal feedback, we know from EQ 4-1 on page 4-25 that the maximum achievable output frequency from the primary output is

$$f_{GLA} = f_{CLKA} \times m / (n \times u) = 2 \text{ MHz} \times 128 / (1 \times 1) = 256 \text{ MHz}$$

EQ 4-5

Figure 4-34 shows the settings of the initial PLL. When configuring the initial PLL, specify the input to be either Hardwired I/O–Driven or External I/O–Driven. This generates a netlist with the initial PLL routed from an I/O. Do not specify the input to be Core Logic–Driven, as this prohibits the connection from the I/O pin to the input of the PLL.

Figure 4-34 • First-Stage PLL Showing Input of 2 MHz and Output of 256 MHz

A second PLL can be connected serially to achieve the required frequency. EQ 4-1 on page 4-25 to EQ 4-3 on page 4-25 are extended as follows:

$$f_{GLA2} = f_{GLA} \times m_2 / (n_2 \times u_2) = f_{CLKA1} \times m_1 \times m_2 / (n_1 \times u_1 \times n_2 \times u_2) - \text{Primary PLL Output Clock} \tag{EQ 4-6}$$

$$f_{GLB2} = f_{YB2} = f_{CLKA1} \times m_1 \times m_2 / (n_1 \times n_2 \times v_1 \times v_2) - \text{Secondary 1 PLL Output Clock(s)} \tag{EQ 4-7}$$

$$f_{GLC2} = f_{YC2} = f_{CLKA1} \times m_1 \times m_2 / (n_1 \times n_2 \times w_1 \times w_2) - \text{Secondary 2 PLL Output Clock(s)} \tag{EQ 4-8}$$

In the example, the final output frequency (f_{output}) from the primary output of the second PLL will be as follows (EQ 4-9):

$$f_{\text{output}} = f_{GLA2} = f_{GLA} \times m_2 / (n_2 \times u_2) = 256 \text{ MHz} \times 70 / (64 \times 1) = 280 \text{ MHz} \tag{EQ 4-9}$$

Figure 4-35 on page 4-49 shows the settings of the second PLL. When configuring the second PLL (or any subsequent-stage PLLs), specify the input to be Core Logic–Driven. This generates a netlist with the second PLL routed internally from the core. Do not specify the input to be Hardwired I/O–Driven or External I/O–Driven, as these options prohibit the connection from the output of the first PLL to the input of the second PLL.

Figure 4-35 • Second-Stage PLL Showing Input of 256 MHz from First Stage and Final Output of 280 MHz

Figure 4-36 shows the simulation results, where the first PLL's output period is 3.9 ns (~256 MHz), and the stage 2 (final) output period is 3.56 ns (~280 MHz).

Figure 4-36 • ModelSim Simulation Results

Recommended Board-Level Considerations

The power to the PLL core is supplied by $V_{CCPLA/B/C/D/E/F}$ (V_{CCPLX}), and the associated ground connections are supplied by $V_{COMPLA/B/C/D/E/F}$ (V_{COMPLX}). When the PLLs are not used, the Actel Designer place-and-route tool automatically disables the unused PLLs to lower power consumption. The user should tie unused V_{CCPLX} and V_{COMPLX} pins to ground. Optionally, the PLL can be turned on/off during normal device operation via the POWERDOWN port (see Table 4-3 on page 4-8).

PLL Power Supply Decoupling Scheme

The PLL core is designed to tolerate noise levels on the PLL power supply as specified in the datasheets. When operated within the noise limits, the PLL will meet the output peak-to-peak jitter specifications specified in the datasheets. User applications should always ensure the PLL power supply is powered from a noise-free or low-noise power source.

However, in situations where the PLL power supply noise level is higher than the tolerable limits, various decoupling schemes can be designed to suppress noise to the PLL power supply. An example is provided in Figure 4-37. The V_{CCPLX} and V_{COMPLX} pins correspond to the PLL analog power supply and ground.

Actel strongly recommends that two ceramic capacitors (10 nF in parallel with 100 nF) be placed close to the power pins (less than 1 inch away). A third generic 10 μ F electrolytic capacitor is recommended for low-frequency noise and should be placed farther away due to its large physical size. Actel recommends that a 6.8 μ H inductor be placed between the supply source and the capacitors to filter out any low-/medium- and high-frequency noise. In addition, the PCB layers should be controlled so the V_{CCPLX} and V_{COMPLX} planes have the minimum separation possible, thus generating a good-quality RF capacitor.

For more recommendations, refer to the [Board-Level Considerations](#) application note.

Recommended 100 nF capacitor:

- Producer BC Components, type X7R, 100 nF, 16 V
- BC Components part number: 0603B104K160BT
- Digi-Key part number: BC1254CT-ND
- Digi-Key part number: BC1254TR-ND

Recommended 10 nF capacitor:

- Surface-mount ceramic capacitor
- Producer BC Components, type X7R, 10 nF, 50 V
- BC Components part number: 0603B103K500BT
- Digi-Key part number: BC1252CT-ND
- Digi-Key part number: BC1252TR-ND

Figure 4-37 • Decoupling Scheme for One PLL (should be replicated for each PLL used)

Conclusion

The advanced CCCs of the IGLOO and ProASIC3 devices are ideal for applications requiring precise clock management. They integrate easily with the internal low-skew clock networks and provide flexible frequency synthesis, clock deskewing, and/or time-shifting operations.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

Part Number 51700094-006-4

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in the Current Version (v1.4)	Page
v1.3 (October 2008)	The "CCC Support in Actel's Flash Devices" section was updated to include IGLOO nano and ProASIC3 nano devices.	4-3
	Figure 4-2 · CCC Options: Global Buffers with No Programmable Delay was revised to add the CLKBIBUF macro.	4-4
	The description of the reference clock was revised in Table 4-2 · Input and Output Description of the CLKDLY Macro.	4-5
	Figure 4-6 · Clock Input Sources (30 k gates devices and below) is new. Figure 4-7 · Clock Input Sources Including CLKBUF, CLKBUF_LVDS/LVPECL, and CLKINT (60 k gates devices and above) applies to 60 k gate devices and above.	4-11
	The "IGLOO and ProASIC3" section was updated to include information for IGLOO nano devices.	4-12
	A note regarding Fusion CCCs was added to Figure 4-8 · Illustration of Hardwired I/O (global input pins) Usage for IGLOO and ProASIC3 devices 60 k Gates and Larger and the name of the figure was changed from Figure 4-8 · Illustration of Hardwired I/O (global input pins) Usage. Figure 4-9 · Illustration of Hardwired I/O (global input pins) Usage for IGLOO and ProASIC3 devices 30 k Gates and Smaller is new.	4-13
	Table 4-5 · Number of CCCs by Device Size and Package was updated to include IGLOO nano and ProASIC3 nano devices. Entries were added to note differences for the CS81, CS121, and CS201 packages.	4-17
	The "Clock Conditioning Circuits without Integrated PLLs" section was rewritten.	4-18
	The "IGLOO and ProASIC3 CCC Locations" section was updated for nano devices.	4-20
	Figure 4-13 · CCC Locations in the 15 k and 30 k Gate Devices was deleted.	4-20
v1.2 (June 2008)	This document was updated to include Fusion and RT ProASIC3 device information. Please review the document very carefully.	N/A
	The "CCC Support in Actel's Flash Devices" section was updated.	4-3
	In the "Global Buffer with Programmable Delay" section, the following sentence was changed from: "In this case, the I/O must be placed in one of the dedicated global I/O locations." To "In this case, the software will automatically place the dedicated global I/O in the appropriate locations."	4-4
	Figure 4-4 · CCC Options: Global Buffers with PLL was updated to include OADIVRST and OADIVHALF.	4-7
	In Figure 4-5 · CCC with PLL Block "fixed delay" was changed to "programmable delay".	4-7
	Table 4-3 · Input and Output Signals of the PLL Block was updated to include OADIVRST and OADIVHALF descriptions.	4-8
	Table 4-7 · Configuration Bit Descriptions for the CCC Blocks was updated to include configuration bits 88 to 81. Note 2 is new. In addition, the description for bit <76:74> was updated.	4-28
	Table 4-15 · Fusion Dynamic CCC Clock Source Selection and Table 4-16 · Fusion Dynamic CCC NGMUX Configuration are new.	4-32

Previous Version	Changes in the Current Version (v1.4)	Page
v1.2 (continued)	Table 4-17 · Fusion Dynamic CCC Division by Half Configuration and Table 4-18 · Configuration Bit <76:75> / VCOSEL<2:1> Selection for All Families are new.	4-33
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 4-1 · Overview of the CCCs Offered in Fusion, IGLOO, and ProASIC3: <ul style="list-style-type: none"> • ProASIC3L was updated to include 1.5 V. • The number of PLLs for ProASIC3E was changed from five to six. 	4-1
v1.0 (January 2008)	Table 4-1 · Flash-Based FPGAs and the associated text were updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "ProASIC3 Terminology" section are new.	4-3
	The "Global Input Selections" section was updated to include 15 k gate devices as supported I/O types for globals, for CCC only.	4-10
	Table 4-5 · Number of CCCs by Device Size and Package was revised to include ProASIC3L, IGLOO PLUS, A3P015, AGL015, AGLP030, AGLP060, and AGLP125.	4-17
	The "IGLOO and ProASIC3 CCC Locations" section was revised to include 15 k gate devices in the exception statements, as they do not contain PLLs.	4-20
51900133-0/5.06	Information about unlocking the PLL was removed from the "Dynamic PLL Configuration" section.	4-26
	In the "Dynamic PLL Configuration" section, information was added about running Layout and determining the exact setting of the ports.	4-38
	In Table 4-7 · Configuration Bit Descriptions for the CCC Blocks, the following bits were updated to delete "transport to the user" and reference the footnote at the bottom of the table: 79 to 71.	4-28

Embedded Memories

5 – FlashROM in Actel’s Low-Power Flash Devices

Introduction

The Fusion, IGLOO®, and ProASIC®3 families of low-power flash-based devices have a dedicated nonvolatile FlashROM memory of 1,024 bits, which provides a unique feature in the FPGA market. The FlashROM can be read, modified, and written using the JTAG (or UJTAG) interface. It can be read but not modified from the FPGA core. Only low-power flash devices contain on-chip user nonvolatile memory (NVM).

Architecture of User Nonvolatile FlashROM

Low-power flash devices have 1 kbit of user-accessible nonvolatile flash memory on-chip that can be read from the FPGA core fabric. The FlashROM is arranged in eight banks of 128 bits (16 bytes) during programming. The 128 bits in each bank are addressable as 16 bytes during the read-back of the FlashROM from the FPGA core. Figure 5-1 shows the FlashROM logical structure.

The FlashROM can only be programmed via the IEEE 1532 JTAG port. It cannot be programmed directly from the FPGA core. When programming, each of the eight 128-bit banks can be selectively reprogrammed. The FlashROM can only be reprogrammed on a bank boundary. Programming involves an automatic, on-chip bank erase prior to reprogramming the bank. The FlashROM supports synchronous read. The address is latched on the rising edge of the clock, and the new output data is stable after the falling edge of the same clock cycle. For more information, refer to the timing diagrams in the DC and Switching Characteristics chapter of the appropriate datasheet. The FlashROM can be read on byte boundaries. The upper three bits of the FlashROM address from the FPGA core define the bank being accessed. The lower four bits of the FlashROM address from the FPGA core define which of the 16 bytes in the bank is being accessed.

FlashROM Support in Flash-Based Devices

The flash FPGAs listed in [Table 5-1](#) support the FlashROM feature and the functions described in this document.

Table 5-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 5-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 5-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Figure 5-2 • Fusion Device Architecture Overview (AFS600)

Figure 5-3 • ProASIC3 and IGLOO Device Architecture

FlashROM Applications

The SmartGen core generator is used to configure FlashROM content. You can configure each page independently. SmartGen enables you to create and modify regions within a page; these regions can be 1 to 16 bytes long (Figure 5-4).

		Byte Number in Page															
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	3																
	2																
	1																
	0																

Figure 5-4 • FlashROM Configuration

The FlashROM content can be changed independently of the FPGA core content. It can be easily accessed and programmed via JTAG, depending on the security settings of the device. The SmartGen core generator enables each region to be independently updated (described in the "Programming and Accessing FlashROM" section on page 5-6). This enables you to change the FlashROM content on a per-part basis while keeping some regions "constant" for all parts. These features allow the FlashROM to be used in diverse system applications. Consider the following possible uses of FlashROM:

- Internet protocol (IP) addressing (wireless or fixed)
- System calibration settings
- Restoring configuration after unpredictable system power-down
- Device serialization and/or inventory control
- Subscription-based business models (e.g., set-top boxes)
- Secure key storage
- Asset management tracking
- Date stamping
- Version management

FlashROM Security

Low-power flash devices have an on-chip Advanced Encryption Standard (AES) decryption core, combined with an enhanced version of the Actel flash-based lock technology (FlashLock®). Together, they provide unmatched levels of security in a programmable logic device. This security applies to both the FPGA core and FlashROM content. These devices use the 128-bit AES (Rijndael) algorithm to encrypt programming files for secure transmission to the on-chip AES decryption core. The same algorithm is then used to decrypt the programming file. This key size provides approximately 3.4×10^{38} possible 128-bit keys. A computing system that could find a DES key in a second would take approximately 149 trillion years to crack a 128-bit AES key. The 128-bit FlashLock feature in low-power flash devices works via a FlashLock security Pass Key mechanism, where the user locks or unlocks the device with a user-defined key. Refer to [Security in Low-Power Flash Devices](#).

If the device is locked with certain security settings, functions such as device read, write, and erase are disabled. This unique feature helps to protect against invasive and noninvasive attacks. Without the correct Pass Key, access to the FPGA is denied. To gain access to the FPGA, the device first must be unlocked using the correct Pass Key. During programming of the FlashROM or the FPGA core, you can generate the security header programming file, which is used to program the AES key and/or FlashLock Pass Key. The security header programming file can also be generated independently of the FlashROM and FPGA core content. The FlashLock Pass Key is not stored in the FlashROM.

Low-power flash devices with AES-based security allow for secure remote field updates over public networks such as the Internet, and ensure that valuable intellectual property (IP) remains out of the hands of IP thieves. [Figure 5-5](#) shows this flow diagram.

Figure 5-5 • Programming FlashROM Using AES

Programming and Accessing FlashROM

The FlashROM content can only be programmed via JTAG, but it can be read back selectively through the JTAG programming interface, the UJTAG interface, or via direct FPGA core addressing. The pages of the FlashROM can be made secure to prevent read-back via JTAG. In that case, read-back on these secured pages is only possible by the FPGA core fabric or via UJTAG.

A 7-bit address from the FPGA core defines which of the eight pages (three MSBs) is being read, and which of the 16 bytes within the selected page (four LSBs) are being read. The FlashROM content can be read on a random basis; the access time is 10 ns for a device supporting commercial specifications. The FPGA core will be powered down during writing of the FlashROM content. FPGA power-down during FlashROM programming is managed on-chip, and FPGA core functionality is not available during programming of the FlashROM. Table 5-2 summarizes various FlashROM access scenarios.

Table 5-2 • FlashROM Read/Write Capabilities by Access Mode

Access Mode	FlashROM Read	FlashROM Write
JTAG	Yes	Yes
UJTAG	Yes	No
FPGA core	Yes	No

Figure 5-6 shows the accessing of the FlashROM using the UJTAG macro. This is similar to FPGA core access, where the 7-bit address defines which of the eight pages (three MSBs) is being read and which of the 16 bytes within the selected page (four LSBs) are being read. Refer to [UJTAG Applications in Actel's Low-Power Flash Devices](#) for details on using the UJTAG macro to read the FlashROM.

Figure 5-7 on page 5-7 and Figure 5-8 on page 5-7 show the FlashROM access from the JTAG port. The FlashROM content can be read on a random basis. The three-bit address defines which page is being read or updated.

Figure 5-6 • Block Diagram of Using UJTAG to Read FlashROM Contents

Figure 5-7 • Accessing FlashROM Using FPGA Core

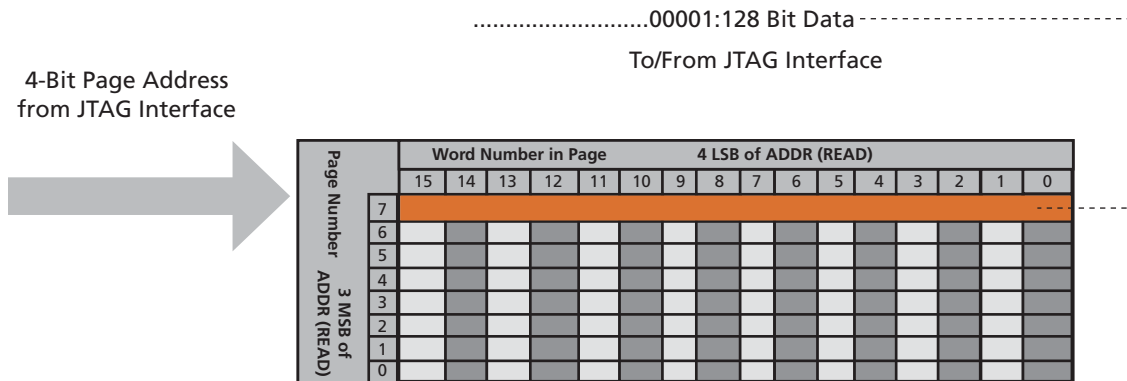

Figure 5-8 • Accessing FlashROM Using JTAG Port

FlashROM Design Flow

The Actel Libero® Integrated Design Environment (IDE) software has extensive FlashROM support, including FlashROM generation, instantiation, simulation, and programming. Figure 5-9 shows the user flow diagram. In the design flow, there are three main steps:

1. FlashROM generation and instantiation in the design
2. Simulation of FlashROM design
3. Programming file generation for FlashROM design

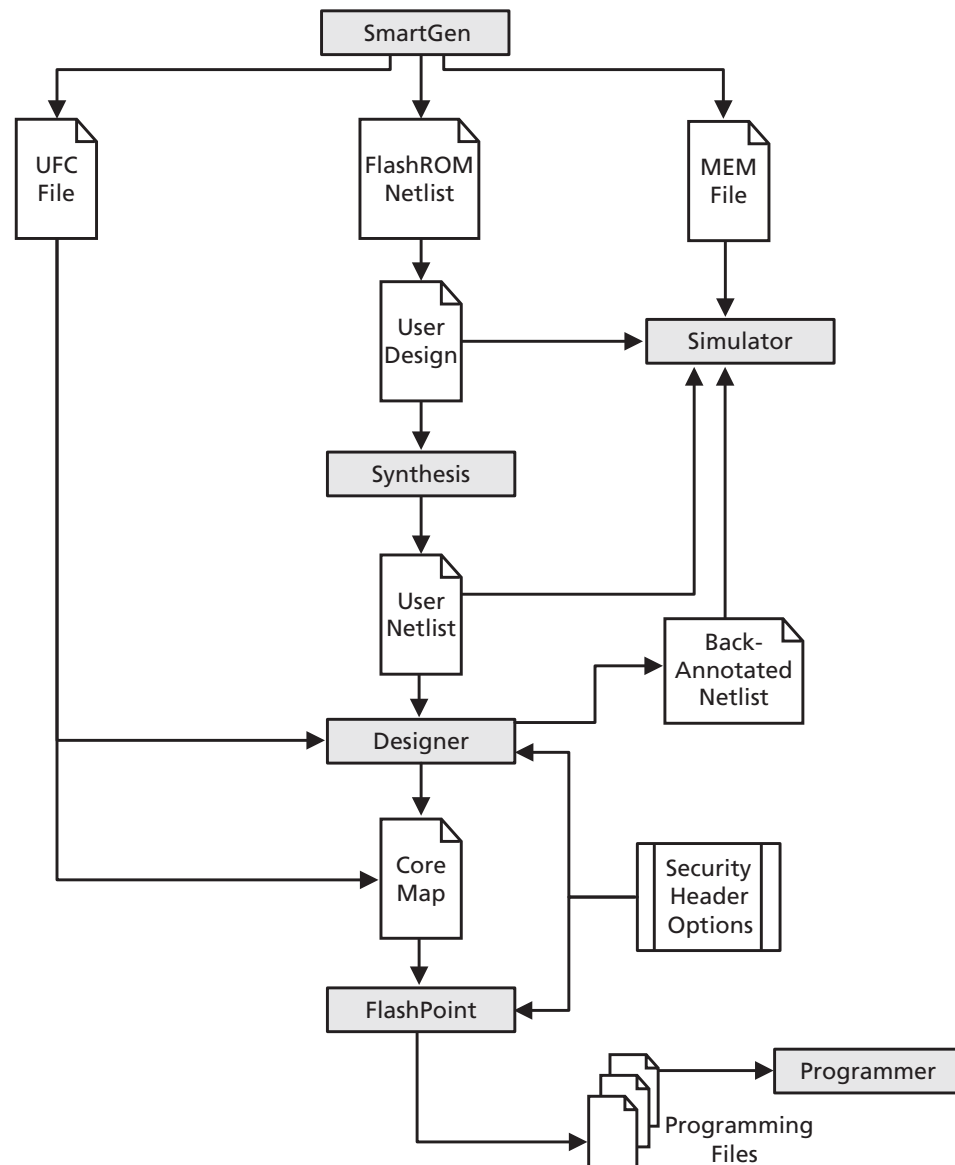

Figure 5-9 • FlashROM Design Flow

FlashROM Generation and Instantiation in the Design

The SmartGen core generator, available in Libero IDE and Designer, is the only tool that can be used to generate the FlashROM content. SmartGen has several user-friendly features to help generate the FlashROM contents. Instead of selecting each byte and assigning values, you can create a region within a page, modify the region, and assign properties to that region. The FlashROM user interface, shown in [Figure 5-10 on page 5-9](#), includes the configuration grid, existing regions list, and properties field. The properties field specifies the region-specific information and defines the data used for that region. You can assign values to the following properties:

1. **Static Fixed Data**—Enables you to fix the data so it cannot be changed during programming time. This option is useful when you have fixed data stored in this region, which is required for the operation of the design in the FPGA. Key storage is one example.
2. **Static Modifiable Data**—Select this option when the data in a particular region is expected to be static data (such as a version number, which remains the same for a long duration but could conceivably change in the future). This option enables you to avoid changing the value every time you enter new data.
3. **Read from File**—This provides the full flexibility of FlashROM usage to the customer. If you have a customized algorithm for generating the FlashROM data, you can specify this setting. You can then generate a text file with data for as many devices as you wish to program, and load that into the FlashPoint programming file generation software to get programming files that include all the data. SmartGen will optionally pass the location of the file where the data is stored if the file is specified in SmartGen. Each text file has only one type of data format (binary, decimal, hex, or ASCII text). The length of each data file must be shorter than or equal to the selected region length. If the data is shorter than the selected region length, the most significant bits will be padded with 0s. For multiple text files for multiple regions, the first lines are for the first device. In SmartGen, **Load Sim. Value From File** allows you to load the first device data in the MEM file for simulation.
4. **Auto Increment/Decrement**—This scenario is useful when you specify the contents of FlashROM for a large number of devices in a series. You can specify the step value for the serial number and a maximum value for inventory control. During programming file generation, the actual number of devices to be programmed is specified and a start value is fed to the software.

Figure 5-10 • SmartGen GUI of the FlashROM

SmartGen allows you to generate the FlashROM netlist in VHDL, Verilog, or EDIF format. After the FlashROM netlist is generated, the core can be instantiated in the main design like other SmartGen cores. Note that the macro library name for FlashROM is UFROM. The following is a sample FlashROM VHDL netlist that can be instantiated in the main design:

```
library ieee;
use ieee.std_logic_1164.all;
library fusion;

entity FROM_a is
  port( ADDR : in std_logic_vector(6 downto 0); DOUT : out std_logic_vector(7 downto 0));
end FROM_a;

architecture DEF_ARCH of FROM_a is

  component UFROM
    generic (MEMORYFILE:string);
    port(DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7 : out std_logic;
        ADDR0, ADDR1, ADDR2, ADDR3, ADDR4, ADDR5, ADDR6 : in std_logic := 'U') ;
  end component;

  component GND
    port( Y : out std_logic);
  end component;

  signal U_7_PIN2 : std_logic ;

begin

  GND_1_net : GND port map(Y => U_7_PIN2);
  UFROM0 : UFROM
  generic map(MEMORYFILE => "FROM_a.mem")
  port map(DO0 => DOUT(0), DO1 => DOUT(1), DO2 => DOUT(2), DO3 => DOUT(3), DO4 => DOUT(4),
    DO5 => DOUT(5), DO6 => DOUT(6), DO7 => DOUT(7), ADDR0 => ADDR(0), ADDR1 => ADDR(1),
    ADDR2 => ADDR(2), ADDR3 => ADDR(3), ADDR4 => ADDR(4), ADDR5 => ADDR(5),
    ADDR6 => ADDR(6));

end DEF_ARCH;
```

SmartGen generates the following files along with the netlist. These are located in the SmartGen folder for the Libero IDE project.

1. MEM (Memory Initialization) file
2. UFC (User Flash Configuration) file
3. Log file

The MEM file is used for simulation, as explained in the "[Simulation of FlashROM Design](#)" section. The UFC file, generated by SmartGen, has the FlashROM configuration for single or multiple devices and is used during STAPL generation. It contains the region properties and simulation values. Note that any changes in the MEM file will not be reflected in the UFC file. Do not modify the UFC to change FlashROM content. Instead, use the SmartGen GUI to modify the FlashROM content. See the "[Programming File Generation for FlashROM Design](#)" section on page 5-11 for a description of how the UFC file is used during the programming file generation. The log file has information regarding the file type and file location.

Simulation of FlashROM Design

The MEM file has 128 rows of 8 bits, each representing the contents of the FlashROM used for simulation. For example, the first row represents page 0, byte 0; the next row is page 0, byte 1; and so the pattern continues. Note that the three MSBs of the address define the page number, and the four LSBs define the byte number. So, if you send address 0000100 to FlashROM, this corresponds to the page 0 and byte 4 location, which is the fifth row in the MEM file. SmartGen defaults to 0s for any unspecified location of the FlashROM. Besides using the MEM file generated by SmartGen, you can create a binary file with 128 rows of 8 bits each and use this as a MEM file. Actel recommends that you use different file names if you plan to generate multiple MEM files. During simulation, Libero IDE passes the MEM file used as the generic file in the netlist, along with the design files and testbench. If you want to use different MEM files during simulation, you need to modify the generic file reference in the netlist.

```

.....
UFROM0: UFROM
--generic map(MEMORYFILE => "F:\Appnotes\FROM\test_designs\testa\smartgen\FROM_a.mem")
--generic map(MEMORYFILE => "F:\Appnotes\FROM\test_designs\testa\smartgen\FROM_b.mem")
.....

```

The VITAL and Verilog simulation models accept the generics passed by the netlist, read the MEM file, and perform simulation with the data in the file.

Programming File Generation for FlashROM Design

FlashPoint is the programming software used to generate the programming files for flash devices. Depending on the applications, you can use the FlashPoint software to generate a STAPL file with different FlashROM contents. In each case, optional AES decryption is available. To generate a STAPL file that contains the same FPGA core content and different FlashROM contents, the FlashPoint software needs an Array Map file for the core and UFC file(s) for the FlashROM. This final STAPL file represents the combination of the logic of the FPGA core and FlashROM content.

FlashPoint generates the STAPL files you can use to program the desired FlashROM page and/or FPGA core of the FPGA device contents. FlashPoint supports the encryption of the FlashROM content and/or FPGA Array configuration data. In the case of using the FlashROM for device serialization, a sequence of unique FlashROM contents will be generated. When generating a programming file with multiple unique FlashROM contents, you can specify in FlashPoint whether to include all FlashROM content in a single STAPL file or generate a different STAPL file for each FlashROM (Figure 5-11). The programming software (FlashPro) handles the single STAPL file that contains the FlashROM content from multiple devices. It enables you to program the FlashROM content into a series of devices sequentially (Figure 5-11). See the *FlashPro User's Guide* for information on serial programming.

Figure 5-11 • Single or Multiple Programming File Generation

Figure 5-12 shows the programming file generator, which enables different STAPL file generation methods. When you select **Program FlashROM** and choose the UFC file, the FlashROM Settings window appears, as shown in Figure 5-13. In this window, you can select the FlashROM page you want to program and the data value for the configured regions. This enables you to use a different page for different programming files.

Figure 5-12 • Programming File Generator

Figure 5-13 • Setting FlashROM during Programming File Generation

The programming hardware and software can load the FlashROM with the appropriate STAPL file. Programming software handles the single STAPL file that contains multiple FlashROM contents for multiple devices, and programs the FlashROM in sequential order (e.g., for device serialization).

This feature is supported in the programming software. After programming with the STAPL file, you can run **DEVICE_INFO** to check the FlashROM content.

DEVICE_INFO displays the FlashROM content, serial number, Design Name, and checksum, as shown below:

```
EXPORT IDCODE[32] = 123261CF
EXPORT SILSIG[32] = 00000000
User information :
CHECKSUM: 61A0
Design Name:      TOP
Programming Method: STAPL
Algorithm Version: 1
Programmer: UNKNOWN
=====
FlashROM Information :
EXPORT Region_7_0[128] = FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF
=====
Security Setting :
Encrypted FlashROM Programming Enabled.
Encrypted FPGA Array Programming Enabled.
=====
```

The Libero IDE file manager recognizes the UFC and MEM files and displays them in the appropriate view. Libero IDE also recognizes the multiple programming files if you choose the option to generate multiple files for multiple FlashROM contents in Designer. These features enable a user-friendly flow for the FlashROM generation and programming in Libero IDE.

Custom Serialization Using FlashROM

You can use FlashROM for device serialization or inventory control by using the Auto Inc region or Read From File region. FlashPoint will automatically generate the serial number sequence for the Auto Inc region with the **Start Value**, **Max Value**, and **Step Value** provided. If you have a unique serial number generation scheme that you prefer, the Read From File region allows you to import the file with your serial number scheme programmed into the region. See the [FlashPro User's Guide](#) for custom serialization file format information.

The following steps describe how to perform device serialization or inventory control using FlashROM:

1. Generate FlashROM using SmartGen. From the **Properties** section in the **FlashROM Settings** dialog box, select the **Auto Inc** or **Read From File** region. For the **Auto Inc** region, specify the desired step value. You will not be able to modify this value in the FlashPoint software.
2. Go through the regular design flow and finish place-and-route.
3. Select **Programming File** in Designer and open **Generate Programming File** (Figure 5-12 on page 5-12).
4. Click **Program FlashROM**, browse to the UFC file, and click **Next**. The FlashROM Settings window appears, as shown in Figure 5-13 on page 5-12.
5. Select the FlashROM page you want to program and the data value for the configured regions. The STAPL file generated will contain only the data that targets the selected FlashROM page.
6. Modify properties for the serialization.
 - For the Auto Inc region, specify the **Start** and **Max** values.
 - For the Read From File region, select the file name of the custom serialization file.
7. Select the FlashROM programming file type you want to generate from the two options below:
 - Single programming file for all devices: generates one programming file with all FlashROM values.
 - One programming file per device: generates a separate programming file for each FlashROM value.

8. Enter the number of devices you want to program and generate the required programming file.
9. Open the programming software and load the programming file. The programming software, FlashPro3 and Silicon Sculptor II, supports the device serialization feature. If, for some reason, the device fails to program a part during serialization, the software allows you to reuse or skip the serial data. Refer to the *FlashPro User's Guide* for details.

Conclusion

The Fusion, IGLOO, and ProASIC3 families are the only FPGAs that offer on-chip FlashROM support. This document presents information on the FlashROM architecture, possible applications, programming, access through the JTAG and UJTAG interface, and integration into your design. In addition, the Libero IDE tool set enables easy creation and modification of the FlashROM content.

The nonvolatile FlashROM block in the FPGA can be customized, enabling multiple applications.

Additionally, the security offered by the low-power flash devices keeps both the contents of FlashROM and the FPGA design safe from system over-builders, system cloners, and IP thieves.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

Part Number 51700094-007-4

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 5-1 · Flash-Based FPGAs .	5-2
v1.2 (June 2008)	The " FlashROM Support in Flash-Based Devices " section was revised to include new families and make the information more concise.	5-2
	Figure 5-2 · Fusion Device Architecture Overview (AFS600) was replaced. Figure 5-5 · Programming FlashROM Using AES was revised to change "Fusion" to "Flash Device."	5-3, 5-5
	The <i>FlashPoint User's Guide</i> was removed from the " User's Guides " section, as its content is now part of the <i>FlashPro User's Guide</i> .	5-14
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 5-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> ProASIC3L was updated to include 1.5 V. The number of PLLs for ProASIC3E was changed from five to six. 	5-2
v1.0 (January 2008)	The chapter was updated to include the IGLOO PLUS family and information regarding 15 k gate devices. The " IGLOO Terminology " section and " ProASIC3 Terminology " section are new.	N/A

6 – SRAM and FIFO Memories in Actel's Low-Power Flash Devices

Introduction

As design complexity grows, greater demands are placed upon an FPGA's embedded memory. Actel Fusion,® IGLOO,® and ProASIC®3 devices provide the flexibility of true dual-port and two-port SRAM blocks. The embedded memory, along with built-in, dedicated FIFO control logic, can be used to create cascading RAM blocks and FIFOs without using additional logic gates.

IGLOO, IGLOO PLUS, and ProASIC3L FPGAs contain an additional feature that allows the device to be put in a low-power mode called Flash*Freeze. In this mode, the core draws minimal power (on the order of 2 to 127 μ W) and still retains values on the embedded SRAM/FIFO and registers. Flash*Freeze technology allows the user to switch to Active mode on demand, thus simplifying power management and the use of SRAM/FIFOs.

Device Architecture

The low-power flash devices feature up to 504 kbits of RAM in 4,608-bit blocks (Figure 6-1 on page 6-2 and Figure 6-2 on page 6-3). The total embedded SRAM for each device can be found in the datasheets. These memory blocks are arranged along the top and bottom of the device to allow better access from the core and I/O (in some devices, they are only available on the north side of the device). Every RAM block has a flexible, hardwired, embedded FIFO controller, enabling the user to implement efficient FIFOs without sacrificing user gates.

In the IGLOO and ProASIC3 families of devices, the following memories are supported:

- 30 k gate devices and smaller do not support SRAM and FIFO.
- 60 k and 125 k gate devices support memories on the north side of the device only.
- 250 k devices and larger support memories on the north and south sides of the device.

In Fusion devices, the following memories are supported:

- AFS090 and AFS250 support memories on the north side of the device only.
- AFS600 and AFS1500 support memories on the north and south sides of the device.

Notes:

1. AES decryption not supported in 30 k gate devices and smaller.
2. Flash*Freeze is supported in all IGLOO devices and the ProASIC3L devices.

Figure 6-1 • IGLOO and ProASIC3 Device Architecture Overview

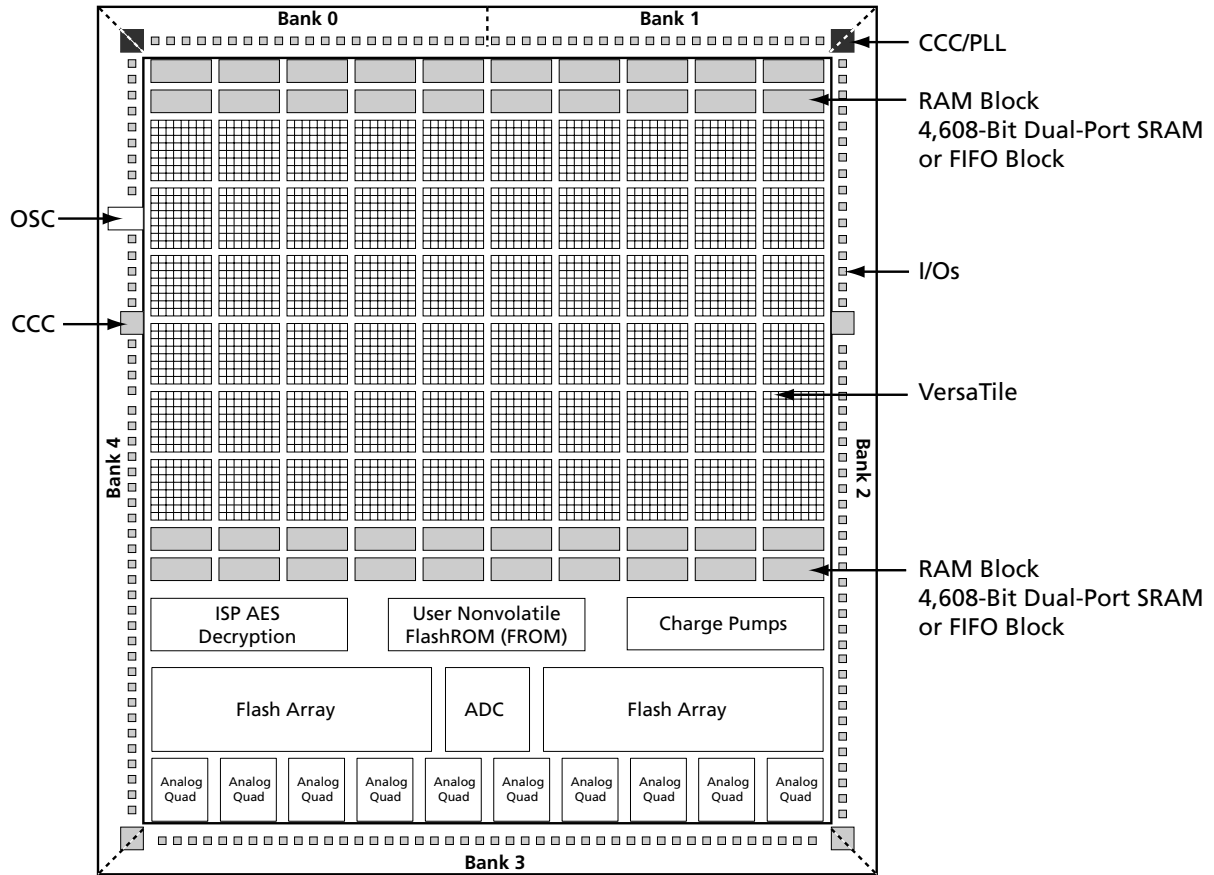

Figure 6-2 • Fusion Device Architecture Overview (AFS600)

SRAM/FIFO Support in Flash-Based Devices

The flash FPGAs listed in [Table 6-1](#) support SRAM and FIFO blocks and the functions described in this document.

Table 6-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 6-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 6-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

SRAM and FIFO Architecture

To meet the needs of high-performance designs, the memory blocks operate strictly in synchronous mode for both read and write operations. The read and write clocks are completely independent, and each can operate at any desired frequency up to 250 MHz.

- 4k×1, 2k×2, 1k×4, 512×9 (dual-port RAM—2 read / 2 write or 1 read / 1 write)
- 512×9, 256×18 (2-port RAM—1 read / 1 write)
- Sync write, sync pipelined / nonpipelined read

Automotive ProASIC3 devices support single-port SRAM capabilities or dual-port SRAM only under specific conditions. Dual-port mode is supported if the clocks to the two SRAM ports are the same and 180° out of phase (i.e., the port A clock is the inverse of the port B clock). The Actel Libero® Integrated Design Environment (IDE) software macro libraries support a dual-port macro only. For use of this macro as a single-port SRAM, the inputs and clock of one port should be tied off (grounded) to prevent errors during design compile. For use in dual-port mode, the same clock with an inversion between the two clock pins of the macro should be used in the design to prevent errors during compile.

The memory block includes dedicated FIFO control logic to generate internal addresses and external flag logic (FULL, EMPTY, AFULL, AEMPTY).

Simultaneous dual-port read/write and write/write operations at the same address are allowed when certain timing requirements are met.

During RAM operation, addresses are sourced by the user logic, and the FIFO controller is ignored. In FIFO mode, the internal addresses are generated by the FIFO controller and routed to the RAM array by internal MUXes.

The low-power flash device architecture enables the read and write sizes of RAMs to be organized independently, allowing for bus conversion. For example, the write size can be set to 256×18 and the read size to 512×9.

Both the write width and read width for the RAM blocks can be specified independently with the WW (write width) and RW (read width) pins. The different D×W configurations are 256×18, 512×9, 1k×4, 2k×2, and 4k×1. When widths of one, two, or four are selected, the ninth bit is unused. For example, when writing nine-bit values and reading four-bit values, only the first four bits and the second four bits of each nine-bit value are addressable for read operations. The ninth bit is not accessible.

Conversely, when writing four-bit values and reading nine-bit values, the ninth bit of a read operation will be undefined. The RAM blocks employ little-endian byte order for read and write operations.

Memory Blocks and Macros

Memory blocks can be configured with many different aspect ratios, but are generically supported in the macro libraries as one of two memory elements: RAM4K9 or RAM512X18. The RAM4K9 is configured as a true dual-port memory block, and the RAM512X18 is configured as a two-port memory block. Dual-port memory allows the RAM to both read from and write to either port independently. Two-port memory allows the RAM to read from one port and write to the other using a common clock or independent read and write clocks. If needed, the RAM4K9 blocks can be configured as two-port memory blocks. The memory block can be configured as a FIFO by combining the basic memory block with dedicated FIFO controller logic. The FIFO macro is named FIFO4KX18 (Figure 6-3 on page 6-6).

Clocks for the RAM blocks can be driven by the VersaNet (global resources) or by regular nets. When using local clock segments, the clock segment region that encompasses the RAM blocks can drive the RAMs. In the dual-port configuration (RAM4K9), each memory block port can be driven by either rising-edge or falling-edge clocks. Each port can be driven by clocks with different edges. Though only a rising-edge clock can drive the physical block itself, the Actel Designer software will automatically bubble-push the inversion to properly implement the falling-edge trigger for the RAM block.

Note: Automotive ProASIC3 devices restrict RAM4K9 to a single port or to dual ports with the same clock 180° out of phase (inverted) between clock pins. In single-port mode, inputs to port B should be tied to ground to prevent errors during compile. For FIFO4K18, the same clock 180° out of phase (inverted) between clock pins should be used.

Figure 6-3 • Supported Basic RAM Macros

SRAM Features

RAM4K9 Macro

RAM4K9 is the dual-port configuration of the RAM block (Figure 6-4). The RAM4K9 nomenclature refers to both the deepest possible configuration and the widest possible configuration the dual-port RAM block can assume, and does not denote a possible memory aspect ratio. The RAM block can be configured to the following aspect ratios: 4,096×1, 2,048×2, 1,024×4, and 512×9. RAM4K9 is fully synchronous and has the following features:

- Two ports that allow fully independent reads and writes at different frequencies
- Selectable pipelined or nonpipelined read
- Active-low block enables for each port
- Toggle control between read and write mode for each port
- Active-low asynchronous reset
- Pass-through write data or hold existing data on output. In pass-through mode, the data written to the write port will immediately appear on the read port.
- Designer software will automatically facilitate falling-edge clocks by bubble-pushing the inversion to previous stages.

Note: For timing diagrams of the RAM signals, refer to the appropriate family datasheet.

Figure 6-4 • RAM4K9 Simplified Configuration

Signal Descriptions for RAM4K9

Note: Automotive ProASIC3 devices support single-port SRAM capabilities, or dual-port SRAM only under specific conditions. Dual-port mode is supported if the clocks to the two SRAM ports are the same and 180° out of phase (i.e., the port A clock is the inverse of the port B clock). Since Actel Libero IDE macro libraries support a dual-port macro only, certain modifications must be made. These are detailed below.

The following signals are used to configure the RAM4K9 memory element:

WIDTHA and WIDTHB

These signals enable the RAM to be configured in one of four allowable aspect ratios (Table 6-2 on page 6-8).

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, WIDTHB should be tied to ground.

Table 6-2 • Allowable Aspect Ratio Settings for WIDTHA[1:0]

WIDTHA[1:0]	WIDTHB[1:0]	D×W
00	00	4k×1
01	01	2k×2
10	10	1k×4
11	11	512×9

Note: The aspect ratio settings are constant and cannot be changed on the fly.

BLKA and BLKB

These signals are active-low and will enable the respective ports when asserted. When a BLKx signal is deasserted, that port's outputs hold the previous value.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, BLKB should be tied to ground.

WENA and WENB

These signals switch the RAM between read and write modes for the respective ports. A LOW on these signals indicates a write operation, and a HIGH indicates a read.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, WENB should be tied to ground.

CLKA and CLKB

These are the clock signals for the synchronous read and write operations. These can be driven independently or with the same driver.

Note: For Automotive ProASIC3 devices, dual-port mode is supported if the clocks to the two SRAM ports are the same and 180° out of phase (i.e., the port A clock is the inverse of the port B clock). For use of this macro as a single-port SRAM, the inputs and clock of one port should be tied off (grounded) to prevent errors during design compile.

PIPEA and PIPEB

These signals are used to specify pipelined read on the output. A LOW on PIPEA or PIPEB indicates a nonpipelined read, and the data appears on the corresponding output in the same clock cycle. A HIGH indicates a pipelined read, and data appears on the corresponding output in the next clock cycle.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, PIPEB should be tied to ground. For use in dual-port mode, the same clock with an inversion between the two clock pins of the macro should be used in the design to prevent errors during compile.

WMODEA and WMODEB

These signals are used to configure the behavior of the output when the RAM is in write mode. A LOW on these signals makes the output retain data from the previous read. A HIGH indicates pass-through behavior, wherein the data being written will appear immediately on the output. This signal is overridden when the RAM is being read.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, WMODEB should be tied to ground.

RESET

This active-low signal resets the control logic, forces the output hold state registers to zero, disables reads and writes from the SRAM block, and clears the data hold registers when asserted. It does not reset the contents of the memory array.

While the RESET signal is active, read and write operations are disabled. As with any asynchronous reset signal, care must be taken not to assert it too close to the edges of active read and write clocks.

ADDRA and ADDR B

These are used as read or write addresses, and they are 12 bits wide. When a depth of less than 4 k is specified, the unused high-order bits must be grounded (Table 6-3 on page 6-9).

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, ADDR_B should be tied to ground.

Table 6-3 • Address Pins Unused/Used for Various Supported Bus Widths

D×W	ADDR _x	
	Unused	Used
4k×1	None	[11:0]
2k×2	[11]	[10:0]
1k×4	[11:10]	[9:0]
512×9	[11:9]	[8:0]

Note: The "x" in ADDR_x implies A or B.

DINA and DINB

These are the input data signals, and they are nine bits wide. Not all nine bits are valid in all configurations. When a data width less than nine is specified, unused high-order signals must be grounded (Table 6-4).

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, DIN_B should be tied to ground.

DOUTA and DOUTB

These are the nine-bit output data signals. Not all nine bits are valid in all configurations. As with DINA and DINB, high-order bits may not be used (Table 6-4). The output data on unused pins is undefined.

Table 6-4 • Unused/Used Input and Output Data Pins for Various Supported Bus Widths

D×W	DIN _x /DOUT _x	
	Unused	Used
4k×1	[8:1]	[0]
2k×2	[8:2]	[1:0]
1k×4	[8:4]	[3:0]
512×9	None	[8:0]

Note: The "x" in DIN_x or DOUT_x implies A or B.

RAM512X18 Macro

RAM512X18 is the two-port configuration of the same RAM block (Figure 6-5 on page 6-10). Like the RAM4K9 nomenclature, the RAM512X18 nomenclature refers to both the deepest possible configuration and the widest possible configuration the two-port RAM block can assume. In two-port mode, the RAM block can be configured to either the 512×9 aspect ratio or the 256×18 aspect ratio. RAM512X18 is also fully synchronous and has the following features:

- Dedicated read and write ports
- Active-low read and write enables
- Selectable pipelined or nonpipelined read
- Active-low asynchronous reset
- Designer software will automatically facilitate falling-edge clocks by bubble-pushing the inversion to previous stages.

Note: For timing diagrams of the RAM signals, refer to the appropriate family datasheet.

Figure 6-5 • 512X18 Two-Port RAM Block Diagram

Signal Descriptions for RAM512X18

RAM512X18 has slightly different behavior from RAM4K9, as it has dedicated read and write ports.

WW and RW

These signals enable the RAM to be configured in one of the two allowable aspect ratios (Table 6-5).

Table 6-5 • Aspect Ratio Settings for WW[1:0]

WW[1:0]	RW[1:0]	D×W
01	01	512×9
10	10	256×18
00, 11	00, 11	Reserved

WD and RD

These are the input and output data signals, and they are 18 bits wide. When a 512×9 aspect ratio is used for write, WD[17:9] are unused and must be grounded. If this aspect ratio is used for read, RD[17:9] are undefined.

WADDR and RADDR

These are read and write addresses, and they are nine bits wide. When the 256×18 aspect ratio is used for write or read, WADDR[8] and RADDR[8] are unused and must be grounded.

WCLK and RCLK

These signals are the write and read clocks, respectively. They can be clocked on the rising or falling edge of WCLK and RCLK.

WEN and REN

These signals are the write and read enables, respectively. They are both active-low by default. These signals can be configured as active-high.

RESET

This active-low signal resets the control logic, forces the output hold state registers to zero, disables reads and writes from the SRAM block, and clears the data hold registers when asserted. It does not reset the contents of the memory array.

While the RESET signal is active, read and write operations are disabled. As with any asynchronous reset signal, care must be taken not to assert it too close to the edges of active read and write clocks.

PIPE

This signal is used to specify pipelined read on the output. A LOW on PIPE indicates a nonpipelined read, and the data appears on the output in the same clock cycle. A HIGH indicates a pipelined read, and data appears on the output in the next clock cycle.

SRAM Usage

The following descriptions refer to the usage of both RAM4K9 and RAM512X18.

Clocking

The dual-port SRAM blocks are only clocked on the rising edge. SmartGen allows falling-edge-triggered clocks by adding inverters to the netlist, hence achieving dual-port SRAM blocks that are clocked on either edge (rising or falling). For dual-port SRAM, each port can be clocked on either edge and by separate clocks by port. Note that for Automotive ProASIC3, the same clock, with an inversion between the two clock pins of the macro, should be used in design to prevent errors during compile.

Low-power flash devices support inversion (bubble-pushing) throughout the FPGA architecture, including the clock input to the SRAM modules. Inversions added to the SRAM clock pin on the design schematic or in the HDL code will be automatically accounted for during design compile without incurring additional delay in the clock path.

The two-port SRAM can be clocked on the rising or falling edge of WCLK and RCLK.

If negative-edge RAM and FIFO clocking is selected for memory macros, clock edge inversion management (bubble-pushing) is automatically used within the development tools, without performance penalty.

Modes of Operation

There are two read modes and one write mode:

- Read Nonpipelined (synchronous—1 clock edge): In the standard read mode, new data is driven onto the RD bus in the same clock cycle following RA and REN valid. The read address is registered on the read port clock active edge, and data appears at RD after the RAM access time. Setting PIPE to OFF enables this mode.
- Read Pipelined (synchronous—2 clock edges): The pipelined mode incurs an additional clock delay from address to data but enables operation at a much higher frequency. The read address is registered on the read port active clock edge, and the read data is registered and appears at RD after the second read clock edge. Setting PIPE to ON enables this mode.
- Write (synchronous—1 clock edge): On the write clock active edge, the write data is written into the SRAM at the write address when WEN is HIGH. The setup times of the write address, write enables, and write data are minimal with respect to the write clock.

RAM Initialization

Each SRAM block can be individually initialized on power-up by means of the JTAG port using the UJTAG mechanism. The shift register for a target block can be selected and loaded with the proper bit configuration to enable serial loading. The 4,608 bits of data can be loaded in a single operation.

FIFO Features

The FIFO4KX18 macro is created by merging the RAM block with dedicated FIFO logic (Figure 6-6 on page 6-12). Since the FIFO logic can only be used in conjunction with the memory block, there is no separate FIFO controller macro. As with the RAM blocks, the FIFO4KX18 nomenclature does not refer to a possible aspect ratio, but rather to the deepest possible data depth and the widest possible data width. FIFO4KX18 can be configured into the following aspect ratios: 4,096×1, 2,048×2, 1,024×4, 512×9, and 256×18. In addition to being fully synchronous, the FIFO4KX18 also has the following features:

- Four FIFO flags: Empty, Full, Almost-Empty, and Almost-Full
- Empty flag is synchronized to the read clock
- Full flag is synchronized to the write clock
- Both Almost-Empty and Almost-Full flags have programmable thresholds

- Active-low asynchronous reset
- Active-low block enable
- Active-low write enable
- Active-high read enable
- Ability to configure the FIFO to either stop counting after the empty or full states are reached or to allow the FIFO counters to continue
- Designer software will automatically facilitate falling-edge clocks by bubble-pushing the inversion to previous stages.

Figure 6-6 • FIFO4KX18 Block Diagram

Figure 6-7 • RAM Block with Embedded FIFO Controller

The FIFOs maintain a separate read and write address. Whenever the difference between the write address and the read address is greater than or equal to the almost-full value (AFVAL), the Almost-Full flag is asserted. Similarly, the Almost-Empty flag is asserted whenever the difference between the write address and read address is less than or equal to the almost-empty value (AEVAL).

Due to synchronization between the read and write clocks, the Empty flag will deassert after the second read clock edge from the point that the write enable asserts. However, since the Empty flag is synchronized to the read clock, it will assert after the read clock reads the last data in the FIFO. Also, since the Full flag is dependent on the actual hardware configuration, it will assert when the actual physical implementation of the FIFO is full.

For example, when a user configures a 128×18 FIFO, the actual physical implementation will be a 256×18 FIFO element. Since the actual implementation is 256×18, the Full flag will not trigger until the 256×18 FIFO is full, even though a 128×18 FIFO was requested. For this example, the Almost-Full flag can be used instead of the Full flag to signal when the 128th data word is reached.

To accommodate different aspect ratios, the almost-full and almost-empty values are expressed in terms of data bits instead of data words. SmartGen translates the user's input, expressed in data words, into data bits internally. SmartGen allows the user to select the thresholds for the Almost-Empty and Almost-Full flags in terms of either the read data words or the write data words, and makes the appropriate conversions for each flag.

After the empty or full states are reached, the FIFO can be configured so the FIFO counters either stop or continue counting. For timing numbers, refer to the appropriate family datasheet.

Signal Descriptions for FIFO4K18

The following signals are used to configure the FIFO4K18 memory element:

WW and RW

These signals enable the FIFO to be configured in one of the five allowable aspect ratios (Table 6-6).

Table 6-6 • Aspect Ratio Settings for WW[2:0]

WW[2:0]	RW[2:0]	D×W
000	000	4k×1
001	001	2k×2
010	010	1k×4
011	011	512×9
100	100	256×18
101, 110, 111	101, 110, 111	Reserved

WBLK and RBLK

These signals are active-low and will enable the respective ports when LOW. When the RBLK signal is HIGH, that port's outputs hold the previous value.

WEN and REN

Read and write enables. WEN is active-low and REN is active-high by default. These signals can be configured as active-high or -low.

WCLK and RCLK

These are the clock signals for the synchronous read and write operations. These can be driven independently or with the same driver.

Note: For the Automotive ProASIC3 FIFO4K18, for the same clock, 180° out of phase (inverted) between clock pins should be used.

RPIPE

This signal is used to specify pipelined read on the output. A LOW on RPIPE indicates a nonpipelined read, and the data appears on the output in the same clock cycle. A HIGH indicates a pipelined read, and data appears on the output in the next clock cycle.

RESET

This active-low signal resets the control logic and forces the output hold state registers to zero when asserted. It does not reset the contents of the memory array (Table 6-7 on page 6-14).

While the RESET signal is active, read and write operations are disabled. As with any asynchronous RESET signal, care must be taken not to assert it too close to the edges of active read and write clocks.

WD

This is the input data bus and is 18 bits wide. Not all 18 bits are valid in all configurations. When a data width less than 18 is specified, unused higher-order signals must be grounded (Table 6-7).

RD

This is the output data bus and is 18 bits wide. Not all 18 bits are valid in all configurations. Like the WD bus, high-order bits become unusable if the data width is less than 18. The output data on unused pins is undefined (Table 6-7).

Table 6-7 • Input Data Signal Usage for Different Aspect Ratios

D×W	WD/RD Unused
4k×1	WD[17:1], RD[17:1]
2k×2	WD[17:2], RD[17:2]
1k×4	WD[17:4], RD[17:4]
512×9	WD[17:9], RD[17:9]
256×18	–

ESTOP, FSTOP

ESTOP is used to stop the FIFO read counter from further counting once the FIFO is empty (i.e., the EMPTY flag goes HIGH). A HIGH on this signal inhibits the counting.

FSTOP is used to stop the FIFO write counter from further counting once the FIFO is full (i.e., the FULL flag goes HIGH). A HIGH on this signal inhibits the counting.

For more information on these signals, refer to the "ESTOP and FSTOP Usage" section on page 6-15.

FULL, EMPTY

When the FIFO is full and no more data can be written, the FULL flag asserts HIGH. The FULL flag is synchronous to WCLK to inhibit writing immediately upon detection of a full condition and to prevent overflows. Since the write address is compared to a resynchronized (and thus time-delayed) version of the read address, the FULL flag will remain asserted until two WCLK active edges after a read operation eliminates the full condition.

When the FIFO is empty and no more data can be read, the EMPTY flag asserts HIGH. The EMPTY flag is synchronous to RCLK to inhibit reading immediately upon detection of an empty condition and to prevent underflows. Since the read address is compared to a resynchronized (and thus time-delayed) version of the write address, the EMPTY flag will remain asserted until two RCLK active edges after a write operation removes the empty condition.

For more information on these signals, refer to the "FIFO Flag Usage Considerations" section on page 6-15.

AFULL, AEMPTY

These are programmable flags and will be asserted on the threshold specified by AFVAL and AEVAL, respectively.

When the number of words stored in the FIFO reaches the amount specified by AEVAL while reading, the AEMPTY output will go HIGH. Likewise, when the number of words stored in the FIFO reaches the amount specified by AFVAL while writing, the AFULL output will go HIGH.

AFVAL, AEVAL

The AEVAL and AFVAL pins are used to specify the almost-empty and almost-full threshold values. They are 12-bit signals. For more information on these signals, refer to the "FIFO Flag Usage Considerations" section on page 6-15.

FIFO Usage

ESTOP and FSTOP Usage

The ESTOP pin is used to stop the read counter from counting any further once the FIFO is empty (i.e., the EMPTY flag goes HIGH). Likewise, the FSTOP pin is used to stop the write counter from counting any further once the FIFO is full (i.e., the FULL flag goes HIGH).

The FIFO counters in the device start the count at zero, reach the maximum depth for the configuration (e.g., 511 for a 512×9 configuration), and then restart at zero. An example application for ESTOP, where the read counter keeps counting, would be writing to the FIFO once and reading the same content over and over without doing another write.

FIFO Flag Usage Considerations

The AEVAL and AFVAL pins are used to specify the 12-bit AEMPTY and AFULL threshold values. The FIFO contains separate 12-bit write address (WADDR) and read address (RADDR) counters. WADDR is incremented every time a write operation is performed, and RADDR is incremented every time a read operation is performed. Whenever the difference between WADDR and RADDR is greater than or equal to AFVAL, the AFULL output is asserted. Likewise, whenever the difference between WADDR and RADDR is less than or equal to AEVAL, the AEMPTY output is asserted. To handle different read and write aspect ratios, AFVAL and AEVAL are expressed in terms of total data bits instead of total data words. When users specify AFVAL and AEVAL in terms of read or write words, the SmartGen tool translates them into bit addresses and configures these signals automatically. SmartGen configures the AFULL flag to assert when the write address exceeds the read address by at least a predefined value. In a 2k×8 FIFO, for example, a value of 1,500 for AFVAL means that the AFULL flag will be asserted after a write when the difference between the write address and the read address reaches 1,500 (there have been at least 1,500 more writes than reads). It will stay asserted until the difference between the write and read addresses drops below 1,500.

The AEMPTY flag is asserted when the difference between the write address and the read address is less than a predefined value. In the example above, a value of 200 for AEVAL means that the AEMPTY flag will be asserted when a read causes the difference between the write address and the read address to drop to 200. It will stay asserted until that difference rises above 200. Note that the FIFO can be configured with different read and write widths; in this case, the AFVAL setting is based on the number of write data entries, and the AEVAL setting is based on the number of read data entries. For aspect ratios of 512×9 and 256×18, only 4,096 bits can be addressed by the 12 bits of AFVAL and AEVAL. The number of words must be multiplied by 8 and 16 instead of 9 and 18. The SmartGen tool automatically uses the proper values. To avoid halfwords being written or read, which could happen if different read and write aspect ratios were specified, the FIFO will assert FULL or EMPTY as soon as at least one word cannot be written or read. For example, if a two-bit word is written and a four-bit word is being read, the FIFO will remain in the empty state when the first word is written. This occurs even if the FIFO is not completely empty, because in this case, a complete word cannot be read. The same is applicable in the full state. If a four-bit word is written and a two-bit word is read, the FIFO is full and one word is read. The FULL flag will remain asserted because a complete word cannot be written at this point.

Variable Aspect Ratio and Cascading

Variable aspect ratio and cascading allow users to configure the memory in the width and depth required. The memory block can be configured as a FIFO by combining the basic memory block with dedicated FIFO controller logic. The FIFO macro is named FIFO4KX18. Low-power flash device RAM can be configured as 1, 2, 4, 9, or 18 bits wide. By cascading the memory blocks, any multiple of those widths can be created. The RAM blocks can be from 256 to 4,096 bits deep, depending on the aspect ratio, and the blocks can also be cascaded to create deeper areas. Refer to the aspect ratios available for each macro cell in the ["SRAM Features" section on page 6-7](#). The largest continuous configurable memory area is equal to half the total memory available on the device, because the RAM is separated into two groups, one on each side of the device.

The Actel SmartGen core generator will automatically configure and cascade both RAM and FIFO blocks. Cascading is accomplished using dedicated memory logic and does not consume user gates for depths up to 4,096 bits deep and widths up to 18, depending on the configuration. Deeper memory will utilize some user gates to multiplex the outputs.

Generated RAM and FIFO macros can be created as either structural VHDL or Verilog for easy instantiation into the design. Users of Actel Libero IDE can create a symbol for the macro and incorporate it into a design schematic.

Table 6-10 on page 6-17 shows the number of memory blocks required for each of the supported depth and width memory configurations, and for each depth and width combination. For example, a 256-bit deep by 32-bit wide two-port RAM would consist of two 256×18 RAM blocks. The first 18 bits would be stored in the first RAM block, and the remaining 14 bits would be implemented in the other 256×18 RAM block. This second RAM block would have four bits of unused storage. Similarly, a dual-port memory block that is 8,192 bits deep and 8 bits wide would be implemented using 16 memory blocks. The dual-port memory would be configured in a 4,096×1 aspect ratio. These blocks would then be cascaded two deep to achieve 8,192 bits of depth, and eight wide to achieve the eight bits of width.

Table 6-8 and Table 6-9 show the maximum potential width and depth configuration for each device. Note that 15 k and 30 k gate devices do not support RAM or FIFO.

Table 6-8 • Memory Availability per IGLOO and ProASIC3 Device

Device		RAM Blocks	Maximum Potential Width ¹		Maximum Potential Depth ²	
IGLOO IGLOO nano IGLOO PLUS	ProASIC3 ProASIC3 nano ProASIC3L		Depth	Width	Depth	Width

Initializing the RAM/FIFO

The SRAM blocks can be initialized with data to use as a lookup table (LUT). Data initialization can be accomplished either by loading the data through the design logic or through the UJTAG interface. The UJTAG macro is used to allow access from the JTAG port to the internal logic in the device. By sending the appropriate initialization string to the JTAG Test Access Port (TAP) Controller, the designer can put the JTAG circuitry into a mode that allows the user to shift data into the array logic through the JTAG port using the UJTAG macro. For a more detailed explanation of the UJTAG macro, refer to *UJTAG Applications in Actel's Low-Power Flash Devices*.

A user interface is required to receive the user command, initialization data, and clock from the UJTAG macro. The interface must synchronize and load the data into the correct RAM block of the design. The main outputs of the user interface block are the following:

- Memory block chip select: Selects a memory block for initialization. The chip selects signals for each memory block that can be generated from different user-defined pockets or simple logic, such as a ring counter (see below).
- Memory block write address: Identifies the address of the memory cell that needs to be initialized.
- Memory block write data: The interface block receives the data serially from the UTDI port of the UJTAG macro and loads it in parallel into the write data ports of the memory blocks.
- Memory block write clock: Drives the WCLK of the memory block and synchronizes the write data, write address, and chip select signals.

Figure 6-8 shows the user interface between UJTAG and the memory blocks.

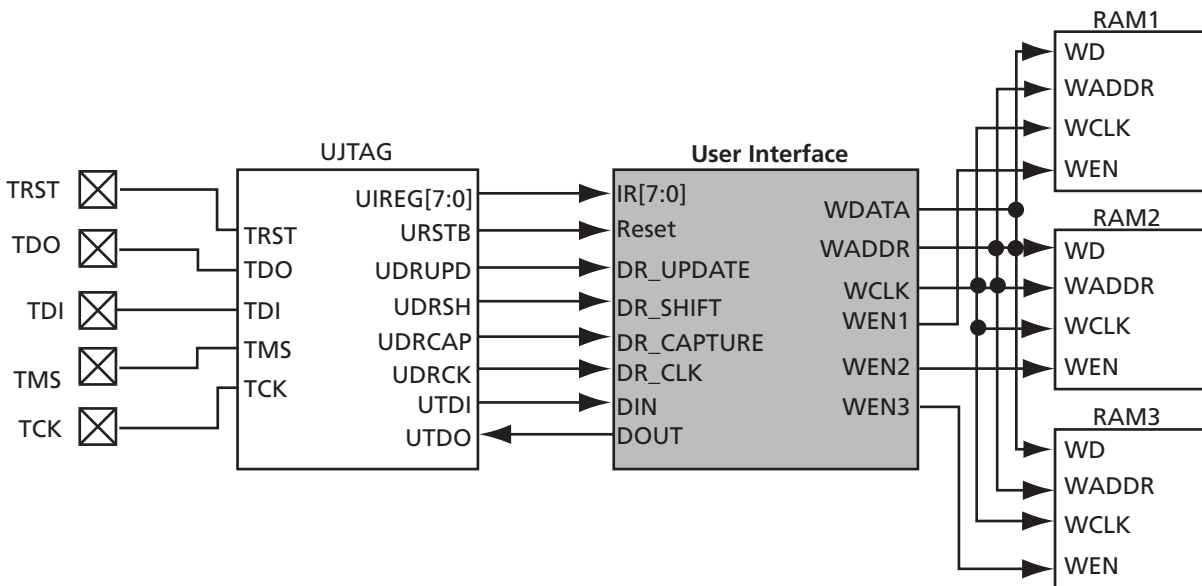

Figure 6-8 • Interfacing TAP Ports and SRAM Blocks

An important component of the interface between the UJTAG macro and the RAM blocks is a serial-in/parallel-out shift register. The width of the shift register should equal the data width of the RAM blocks. The RAM data arrives serially from the UTDI output of the UJTAG macro. The data must be shifted into a shift register clocked by the JTAG clock (provided at the UDRCK output of the UJTAG macro).

Then, after the shift register is fully loaded, the data must be transferred to the write data port of the RAM block. To synchronize the loading of the write data with the write address and write clock, the output of the shift register can be pipelined before driving the RAM block.

The write address can be generated in different ways. It can be imported through the TAP using a different instruction opcode and another shift register, or generated internally using a simple

counter. Using a counter to generate the address bits and sweep through the address range of the RAM blocks is recommended, since it reduces the complexity of the user interface block and the board-level JTAG driver.

Moreover, using an internal counter for address generation speeds up the initialization procedure, since the user only needs to import the data through the JTAG port.

The designer may use different methods to select among the multiple RAM blocks. Using counters along with demultiplexers is one approach to set the write enable signals. Basically, the number of RAM blocks needing initialization determines the most efficient approach. For example, if all the blocks are initialized with the same data, one enable signal is enough to activate the write procedure for all of them at the same time. Another alternative is to use different opcodes to initialize each memory block. For a small number of RAM blocks, using counters is an optimal choice. For example, a ring counter can be used to select from multiple RAM blocks. The clock driver of this counter needs to be controlled by the address generation process.

Once the addressing of one block is finished, a clock pulse is sent to the (ring) counter to select the next memory block.

Figure 6-9 illustrates a simple block diagram of an interface block between UJTAG and RAM blocks.

Figure 6-9 • Block Diagram of a Sample User Interface

In the circuit shown in Figure 6-9, the shift register is enabled by the UDRSH output of the UJTAG macro. The counters and chip select outputs are controlled by the value of the TAP Instruction Register. The comparison block compares the UIREG value with the "start initialization" opcode value (defined by the user). If the result is true, the counters start to generate addresses and activate the WEN inputs of appropriate RAM blocks.

The UDRUPDI output of the UJTAG macro, also shown in Figure 6-9, is used for generating the write clock (WCLK) and synchronizing the data register and address counter with WCLK. UDRUPDI is HIGH when the TAP Controller is in the Data Register Update state, which is an indication of completing the loading of one data word. Once the TAP Controller goes into the Data Register Update state, the UDRUPDI output of the UJTAG macro goes HIGH. Therefore, the pipeline register and the address counter place the proper data and address on the outputs of the interface block. Meanwhile, WCLK is defined as the inverted UDRUPDI. This will provide enough time (equal to the UDRUPDI HIGH time) for the data and address to be placed at the proper ports of the RAM block before the rising edge of WCLK. The inverter is not required if the RAM blocks are clocked at the falling edge of the write clock. An example of this is described in the "Example of RAM Initialization" section on page 6-20.

Example of RAM Initialization

This section of the document presents a sample design in which a 4x4 RAM block is being initialized through the JTAG port. A test feature has been implemented in the design to read back the contents of the RAM after initialization to verify the procedure.

The interface block of this example performs two major functions: initialization of the RAM block and running a test procedure to read back the contents. The clock output of the interface is either the write clock (for initialization) or the read clock (for reading back the contents). The Verilog code for the interface block is included in the "Sample Verilog Code" section on page 6-21.

For simulation purposes, users can declare the input ports of the UJTAG macro for easier assignment in the testbench. However, the UJTAG input ports should not be declared on the top level during synthesis. If the input ports of the UJTAG are declared during synthesis, the synthesis tool will instantiate input buffers on these ports. The input buffers on the ports will cause Compile to fail in Designer.

Figure 6-10 shows the simulation results for the initialization step of the example design.

The CLK_OUT signal, which is the clock output of the interface block, is the inverted DR_UPDATE output of the UJTAG macro. It is clear that it gives sufficient time (while the TAP Controller is in the Data Register Update state) for the write address and data to become stable before loading them into the RAM block.

Figure 6-11 presents the test procedure of the example. The data read back from the memory block matches the written data, thus verifying the design functionality.

Figure 6-10 • Simulation of Initialization Step

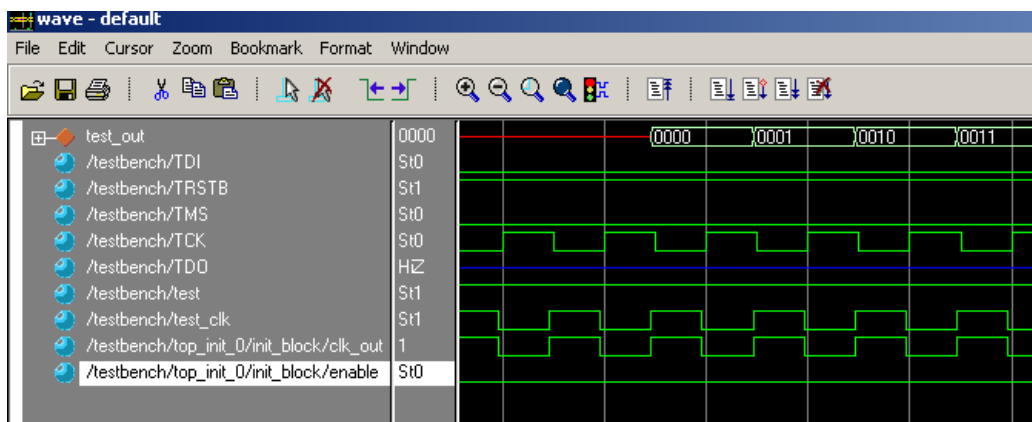

Figure 6-11 • Simulation of the Test Procedure of the Example

The ROM emulation application is based on RAM block initialization. If the user's main design has access only to the read ports of the RAM block (RADDR, RD, RCLK, and REN), and the contents of the RAM are already initialized through the TAP, then the memory blocks will emulate ROM functionality for the core design. In this case, the write ports of the RAM blocks are accessed only by the user interface block, and the interface is activated only by the TAP Instruction Register contents.

Users should note that the contents of the RAM blocks are lost in the absence of applied power. However, the 1 kbit of flash memory, FlashROM, in low-power flash devices can be used to retain data after power is removed from the device. Refer to *FlashROM in Actel's Low-Power Flash Devices* for more information.

Sample Verilog Code

Interface Block

```

`define Initialize_start 8'h22 //INITIALIZATION START COMMAND VALUE
`define Initialize_stop 8'h23 //INITIALIZATION START COMMAND VALUE

module interface(IR, rst_n, data_shift, clk_in, data_update, din_ser, dout_ser, test,
  test_out, test_clk, clk_out, wr_en, rd_en, write_word, read_word, rd_addr, wr_addr);

Software Support

The SmartGen core generator is the easiest way to select and configure the memory blocks (Figure 6-12). SmartGen automatically selects the proper memory block type and aspect ratio, and cascades the memory blocks based on the user's selection. SmartGen also configures any additional signals that may require tie-off.

SmartGen will attempt to use the minimum number of blocks required to implement the desired memory. When cascading, SmartGen will configure the memory for width before configuring for depth. For example, if the user requests a 256×8 FIFO, SmartGen will use a 512×9 FIFO configuration, not 256×18.

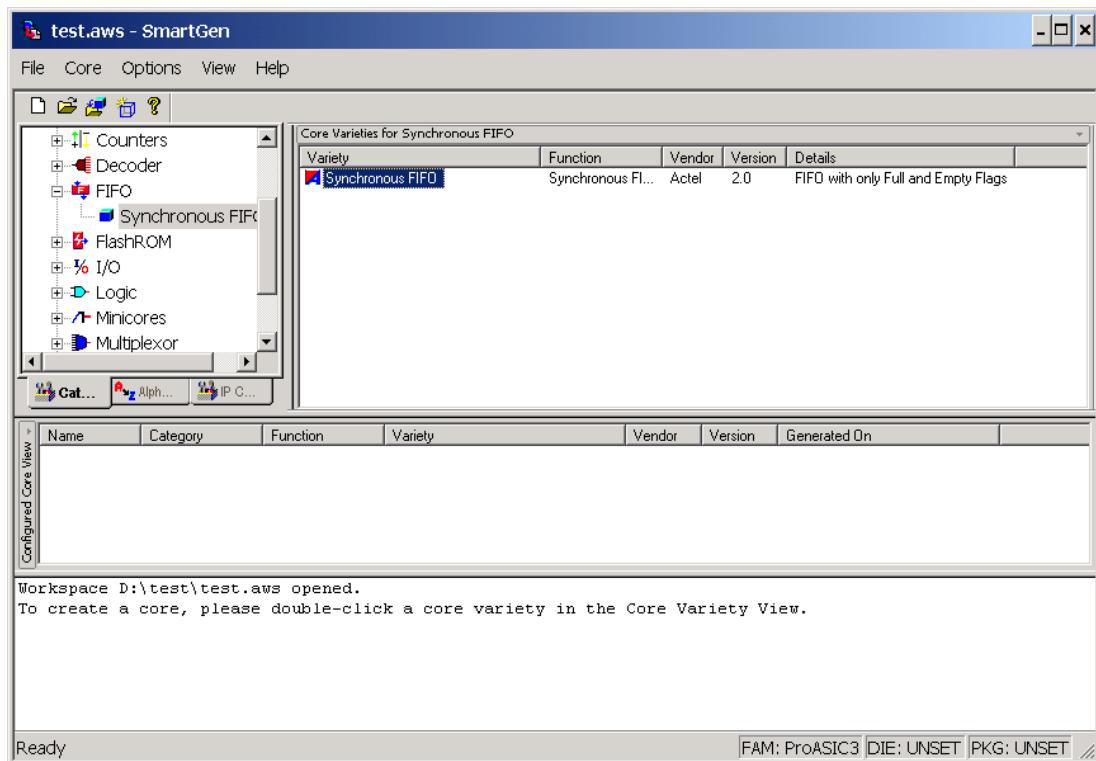

Figure 6-12 • SmartGen Core Generator Interface

SmartGen enables the user to configure the desired RAM element to use either a single clock for read and write, or two independent clocks for read and write. The user can select the type of RAM as well as the width/depth and several other parameters (Figure 6-13).

Figure 6-13 • SmartGen Memory Configuration Interface

SmartGen also has a Port Mapping option that allows the user to specify the names of the ports generated in the memory block (Figure 6-14).

Figure 6-14 • Port Mapping Interface for SmartGen-Generated Memory

SmartGen also configures the FIFO according to user specifications. Users can select no flags, static flags, or dynamic flags. Static flag settings are configured using configuration flash and cannot be altered without reprogramming the device. Dynamic flag settings are determined by register values and can be altered without reprogramming the device by reloading the register values either from the design or through the UJTAG interface described in the "Initializing the RAM/FIFO" section on page 6-18.

SmartGen can also configure the FIFO to continue counting after the FIFO is full. In this configuration, the FIFO write counter will wrap after the counter is full and continue to write data. With the FIFO configured to continue to read after the FIFO is empty, the read counter will also wrap and re-read data that was previously read. This mode can be used to continually read back repeating data patterns stored in the FIFO (Figure 6-15).

Figure 6-15 • SmartGen FIFO Configuration Interface

FIFOs configured using SmartGen can also make use of the port mapping feature to configure the names of the ports.

Limitations

Users should be aware of the following limitations when configuring SRAM blocks for low-power flash devices:

- SmartGen does not track the target device in a family, so it cannot determine if a configured memory block will fit in the target device.
- Dual-port RAMs with different read and write aspect ratios are not supported.
- Cascaded memory blocks can only use a maximum of 64 blocks of RAM.
- The Full flag of the FIFO is sensitive to the maximum depth of the actual physical FIFO block, not the depth requested in the SmartGen interface.

Conclusion

Fusion, IGLOO, and ProASIC3 devices provide users with extremely flexible SRAM blocks for most design needs, with the ability to choose between an easy-to-use dual-port memory or a wide-word two-port memory. Used with the built-in FIFO controllers, these memory blocks also serve as highly efficient FIFOs that do not consume user gates when implemented. The Actel SmartGen core generator provides a fast and easy way to configure these memory elements for use in designs.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

Part Number 51700094-008-5

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in the Current Version (v1.5)	Page
v1.4 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 6-1 · Flash-Based FPGAs .	6-4
	IGLOO nano and ProASIC3 nano devices were added to Table 6-8 · Interfacing TAP Ports and SRAM Blocks .	6-18
v1.3 (August 2008)	The " SRAM/FIFO Support in Flash-Based Devices " section was revised to include new families and make the information more concise.	6-4
	The " SRAM and FIFO Architecture " section was modified to remove "IGLOO and ProASIC3E" from the description of what the memory block includes, as this statement applies to all memory blocks.	6-5
	Wording in the " Clocking " section was revised to change "IGLOO and ProASIC3 devices support inversion" to "Low-power flash devices support inversion." The reference to IGLOO and ProASIC3 development tools in the last paragraph of the section was changed to refer to development tools in general.	6-11
	The " ESTOP and FSTOP Usage " section was updated to refer to FIFO counters in devices in general rather than only IGLOO and ProASIC3E devices.	6-15
v1.2 (June 2008)	The note was removed from Figure 6-7 · RAM Block with Embedded FIFO Controller and placed in the WCLK and RCLK description.	6-12
	The " WCLK and RCLK " description was revised.	6-13
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 6-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> ProASIC3L was updated to include 1.5 V. The number of PLLs for ProASIC3E was changed from five to six. 	6-4
v1.0 (January 2008)	The " Introduction " section was updated to include the IGLOO PLUS family.	6-1
	The " Device Architecture " section was updated to state that 15 k gate devices do not support SRAM and FIFO.	6-1
	The first note in Figure 6-1 · IGLOO and ProASIC3 Device Architecture Overview was updated to include mention of 15 k gate devices, and IGLOO PLUS was added to the second note.	6-3
	Table 6-1 · Flash-Based FPGAs and associated text were updated to include the IGLOO PLUS family. The " IGLOO Terminology " section and " ProASIC3 Terminology " section are new.	6-4
	The text introducing Table 6-8 · Memory Availability per IGLOO and ProASIC3 Device was updated to replace "A3P030 and AGL030" with "15 k and 30 k gate devices." Table 6-8 · Memory Availability per IGLOO and ProASIC3 Device was updated to remove AGL400 and AGL1500 and include IGLOO PLUS and ProASIC3L devices.	6-16

I/O Descriptions and Usage

7 – I/O Structures in nano Devices

Introduction

Low-power flash devices feature a flexible I/O structure, supporting a range of mixed voltages (1.2 V, 1.5 V, 1.8 V, 2.5 V, and 3.3 V) through bank-selectable voltages. IGLOO® and ProASIC3 nano device support Standard I/Os with the addition of Schmitt trigger and hot-swap capability.

Users designing I/O solutions are faced with a number of implementation decisions and configuration choices that can directly impact the efficiency and effectiveness of their final design. The flexible I/O structure, supporting a wide variety of voltages and I/O standards, enables users to meet the growing challenges of their many diverse applications. The Actel Libero® Integrated Design Environment (IDE) provides an easy way to implement I/O that will result in robust I/O design.

This document describes Standard I/O types used for the nano devices in terms of the supported standards. It then explains the individual features and how to implement them in Actel's Libero IDE.

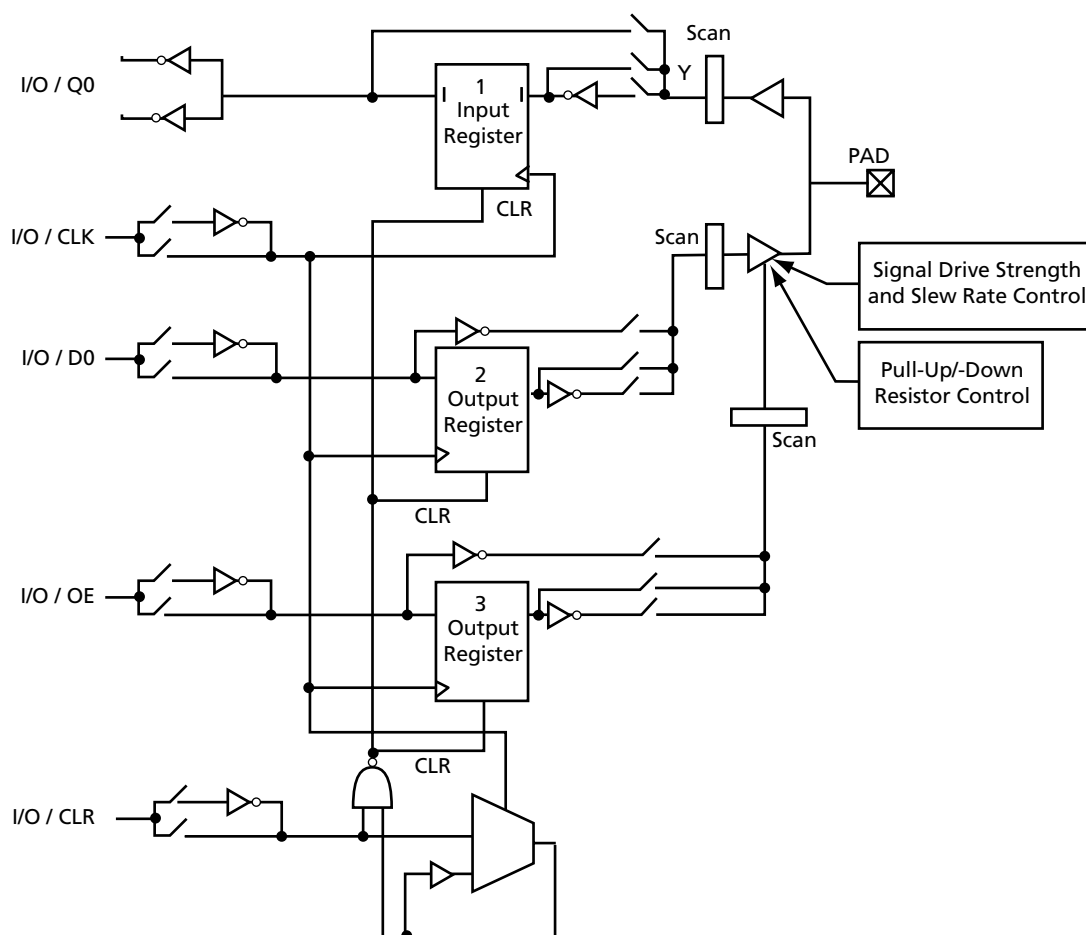

Figure 7-1 • I/O Block Logical Representation for Single-Tile Designs (10 k, 15 k, and 20 k devices)

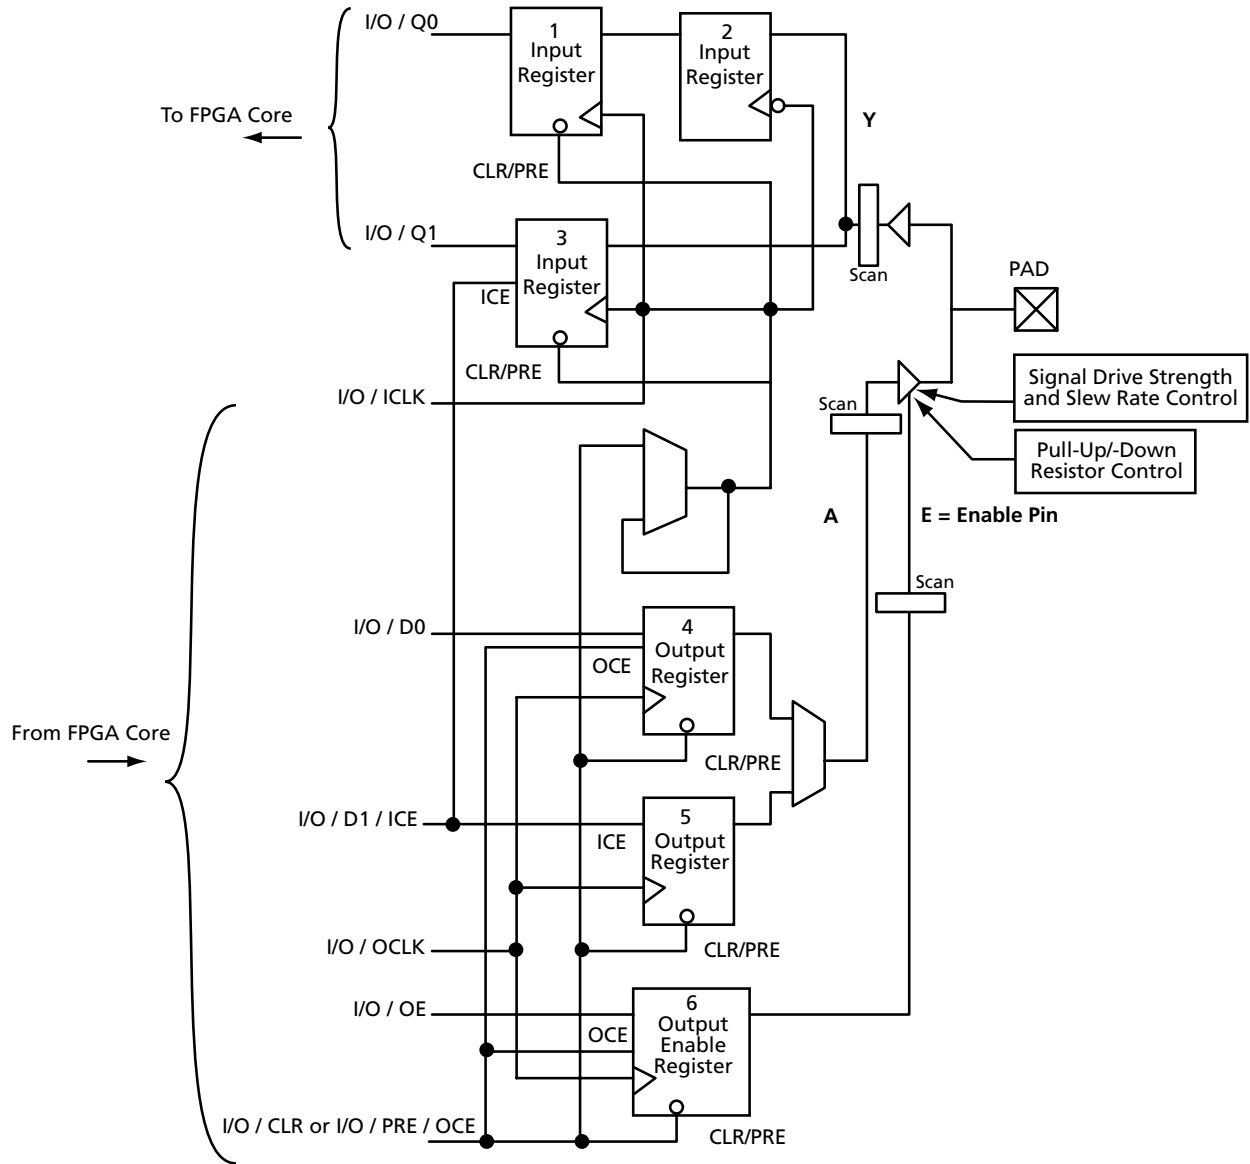

Figure 7-2 • I/O Block Logical Representation for Dual-Tile Designs (60 k, 125 k, and 250 k Devices)

Low-Power Flash Device I/O Support

The low-power flash families listed in [Table 7-1](#) support I/Os and the functions described in this document.

Table 7-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO nano	Lowest-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
ProASIC3	ProASIC3 nano	Lowest-cost 1.5 V FPGAs with balanced performance

Note: *The device name links to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 7-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 7-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

nano Standard I/Os

Table 7-2 and Table 7-4 show the voltages and compatible I/O standards for ProASIC3 nano and IGLOO nano devices.

I/Os provide programmable slew rates, drive strengths, and weak pull-up and pull-down circuits. Selectable Schmitt trigger and 5 V tolerant receivers are offered. See the "5 V Input Tolerance" section on page 7-13 for possible implementations of 5 V tolerance.

All I/Os are in a known state during power-up, and any power-up sequence is allowed without current impact. Refer to the "I/O Power-Up and Supply Voltage Thresholds for Power-On Reset (Commercial and Industrial)" section in the datasheet for more information. During power-up, before reaching activation levels, the I/O input and output buffers are disabled while the weak pull-up is enabled. Activation levels are described in the datasheet.

Table 7-2 • Supported I/O Standards for IGLOO nano Devices

IGLOO nano	AGLN010	AGLN015	AGLN020	AGLN060	AGLN125	AGLN250
Single-Ended

Table 7-3 • Supported I/O Standards for ProASIC3 Devices

ProASIC3 nano	A3PN010	A3PN015	A3PN020	A3PN060	A3PN125	A3PN250
Single-Ended						
LVTTL/LVCMOS 3.3 V, LVCMOS 2.5 V / 1.8 V / 1.5 V	✓	✓	✓	✓	✓	✓

I/O Banks and I/O Standards Compatibility

I/Os are grouped into I/O voltage banks. nano devices have two, three, or four I/O banks.

Each I/O voltage bank has dedicated I/O supply and ground voltages. This isolation is necessary to minimize simultaneous switching noise from the input and output (SSI and SSO). The switching noise (ground bounce and power bounce) is generated by the output buffers and transferred into input buffer circuits, and vice versa. Because of these dedicated supplies, only I/Os with compatible standards can be assigned to the same I/O voltage bank. Table 7-4 shows the required voltage compatibility values for each of these voltages.

There are four I/O banks on the 250 k gate device.

There are three I/O banks on the 15 k and 20 k gate devices.

There are two I/O banks on the 10 k, 60 k, and 125 k gate devices.

I/O standards are compatible if their V_{CCI} values are identical. For more information about I/O and global assignments to I/O banks in a device, refer to the specific pin table for the device in the packaging section of the datasheet and the "User I/O Naming Convention" section on page 7-20.

Table 7-4 • V_{CCI} Voltages and Compatible Standards

V_{CCI} (typical)	Compatible Standards
3.3 V	LVTTL/LVCMOS 3.3
2.5 V	LVCMOS 2.5
1.8 V	LVCMOS 1.8
1.5 V	LVCMOS 1.5
1.2 V	LVCMOS 1.2

Features Supported on Every I/O

Table 7-5 lists all features supported by transmitter/receiver for single-ended I/Os. Table 7-6 lists the performance of each I/O technology.

Table 7-5 • I/O Features

Feature	Description
All I/O	<ul style="list-style-type: none"> High performance (Table 7-6) Electrostatic discharge (ESD) protection I/O register combining option
Single-Ended Transmitter Features	<ul style="list-style-type: none"> Hot-swap I/Os can be configured to behave in Flash*Freeze mode as tristate, HIGH, LOW, or to hold the previous state (not supported on ProASIC3 nano devices). Programmable output slew rate: high and low Optional weak pull-up and pull-down resistors Output drive: 2 drive strengths (except for LVCMOS 1.2 V) LVTTTL/LVCMOS 3.3 V outputs compatible with 5 V TTL inputs
Single-Ended Receiver Features	<ul style="list-style-type: none"> Selectable Schmitt trigger 5 V–input–tolerant receiver (Table 7-12 on page 7-13) Separate ground plane for GNDQ pin and power plane for V_{CCI} pin are used for input buffer to reduce output-induced noise.
DDR	<ul style="list-style-type: none"> DDR is supported for 60 k gate devices and above.

Table 7-6 • Maximum I/O Frequency

Specification	Maximum Performance		
	ProASIC3 nano 1.5 V DC Core Supply Voltage	IGLOO nano V2 or V5 Devices, 1.5 V DC Core Supply Voltage	IGLOO nano V2, 1.2 V DC Core Supply Voltage
LVTTTL/LVCMOS 3.3 V	200 MHz	180 MHz	TBD
LVCMOS 2.5 V	250 MHz	230 MHz	TBD
LVCMOS 1.8 V	200 MHz	180 MHz	TBD
LVCMOS 1.5 V	130 MHz	120 MHz	TBD
LVCMOS 1.2 V	Not supported	TBD	TBD

I/O Architecture

I/O Tile

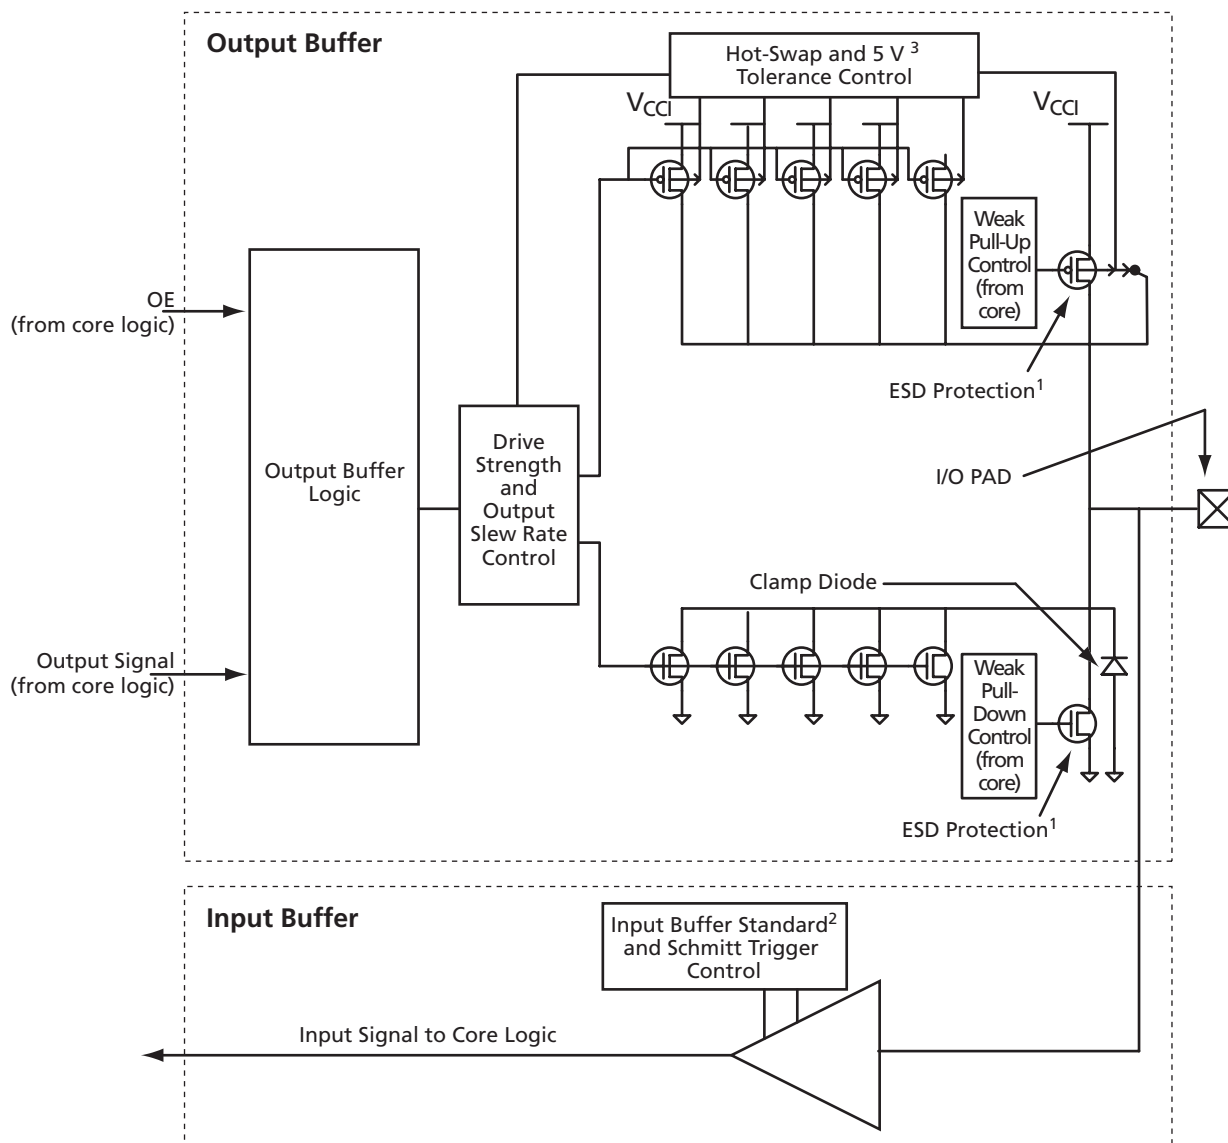

IGLOO and ProASIC3 nano devices utilize either a single-tile or dual-tile I/O architecture ([Figure 7-1 on page 7-1](#) and [Figure 7-2 on page 7-2](#)). The 10 k, 15 k, and 20 k devices utilize the single-tile design and the 60 k, 125 k and 250 k devices utilize the dual-tile design. In both cases, the I/O tile provides a flexible, programmable structure for implementing a large number of I/O standards. In addition, the registers available in the I/O tile can be used to support high-performance register inputs and outputs, with register enable if desired. For single-tile designs, all I/O registers share both the CLR and CLK ports, while for the dual-tile designs, the output register and output enable register share one CLK port. For the dual-tile designs, the registers can also be used to support the JESD-79C Double Data Rate (DDR) standard within the I/O structure (see [DDR for Actel's Low-Power Flash Devices](#) for more information).

I/O Registers

Each I/O module contains several input and output registers. Refer to [Figure 7-3 on page 7-7](#) for a simplified representation of the I/O block. The number of input registers is selected by a set of switches (not shown in [Figure 7-2 on page 7-2](#)) between registers to implement single-ended data transmission to and from the FPGA core. The Designer software sets these switches for the user. For single-tile designs, a common CLR/PRE signal is employed by all I/O registers when I/O register combining is used. The I/O register combining requires that no combinatorial logic be present between the register and the I/O.

I/O Bank Structure

Low-power flash device I/Os are divided into multiple technology banks. The number of banks is device-dependent, supporting two, three, or four banks. Each bank has its own V_{CC1} power supply pin. Refer to Figure 7-2 on page 7-2 for more information.

Notes:

1. All NMOS transistors connected to the I/O pad serve as ESD protection.
2. See Table 7-2 on page 7-4 for available I/O standards.
3. 5 V tolerance requires external resistor.

Figure 7-3 • Simplified I/O Buffer Circuitry

I/O Standards

Single-Ended Standards

These I/O standards use a push-pull CMOS output stage with a voltage referenced to system ground to designate logical states. The input buffer configuration, output drive, and I/O supply voltage (V_{CC}) vary among the I/O standards (Figure 7-4).

Figure 7-4 • Single-Ended I/O Standard Topology

The advantage of these standards is that a common ground can be used for multiple I/Os. This simplifies board layout and reduces system cost. Their low-edge-rate (dv/dt) data transmission causes less electromagnetic interference (EMI) on the board. However, they are not suitable for high-frequency (>200 MHz) switching due to noise impact and higher power consumption.

LVTTTL (Low-Voltage TTL)

This is a general-purpose standard (EIA/JESD8-B) for 3.3 V applications. It uses an LVTTTL input buffer and a push-pull output buffer. The LVTTTL output buffer can have up to six different programmable drive strengths. Refer to "I/O Programmable Features" on page 7-9 for details. Refer to Table 7-14 on page 7-18 for details.

LVC MOS (Low-Voltage CMOS)

The low-power flash devices provide five voltage levels for LVC MOS: LVC MOS 3.3 V, LVC MOS 2.5 V, LVC MOS 1.8 V, LVC MOS 1.5 V, and LVC MOS 1.2 V.

LVC MOS 3.3 V is an extension of the LVC MOS standard (JESD8-B-compliant) used for general-purpose 3.3 V applications. LVC MOS 2.5 V is an extension of the LVC MOS standard (JESD8-5-compliant) used for general-purpose 2.5 V applications. LVC MOS 1.8 V is an extension of the LVC MOS standard (JESD8-7-compliant) used for general-purpose 1.8 V applications. LVC MOS 1.5 V is an extension of the LVC MOS standard (JESD8-11-compliant) used for general-purpose 1.5 V applications. LVC MOS 1.2V is an extension of the LVC MOS standard (JESD8-12A-compliant) used for general-purpose 1.2 V applications.

The V_{CC} values for these standards are 3.3 V, 2.5 V, 1.8 V, 1.5 V, and 1.2 V, respectively. All these versions use a 3.3 V-tolerant CMOS input buffer and a push-pull output buffer. Like LVTTTL, the output buffer has up to four different programmable drive strengths (2, 4, 6, and 8 mA). Refer to "nano Output Drive and Slew" on page 7-18 for details.

Wide Range I/O Support

Actel nano devices support JEDEC defined wide range I/O operation. ProASIC3 nano devices support the JESD8-B specification covering both 3 V and 3.3 V supplies, for an effective operating range of 2.7 V – 3.6 V. IGLOO nano devices support both the JESD8-B specification per the above and JESD8-12A with 1.2 V nominal, supporting an effective operating range of 1.14 V – 1.575 V.

I/O Features

Both IGLOO nano and ProASIC3 nano devices support multiple I/O features that make board design easier. For example, an I/O feature like Schmitt Trigger in the input buffer saves the board space that would be used by an external Schmitt trigger for a slow or noisy input signal. These features are also programmable for each I/O, which in turn gives flexibility in interfacing with other components. The following is a detailed description of all available features in nano devices.

I/O Programmable Features

Low-power flash devices offer many flexible I/O features to support a wide variety of board designs. Some of the features are programmable, with a range for selection. [Table 7-7](#) lists programmable I/O features and their ranges.

Table 7-7 • Programmable I/O Features (user control via I/O Attribute Editor)

Feature	Description	Range
Slew Control	Output slew rate	HIGH, LOW
Output Drive (mA)	Output drive strength	Depends on I/O type
Resistor Pull	Weak resistor pull circuit	Up, Down, None
Schmitt Trigger	Schmitt trigger for input only	ON, OFF

Hot-Swap Support

All nano devices are hot-swappable.

The hot-swap feature appears as a read-only check box in the I/O Attribute Editor that shows whether an I/O is hot-swappable or not. Refer to [Power-Up/Down Behavior of Low-Power Flash Devices](#) for details on hot-swapping.

Hot-swapping is the operation of hot insertion or hot removal of a card in a powered-up system. The levels of hot-swap support and examples of related applications are described in [Table 7-8 on page 7-10](#) to [Table 7-11 on page 7-11](#). The I/Os also need to be configured in hot-insertion mode if hot-plugging compliance is required. nano devices have an I/O structure that allows the support of Level 3 and Level 4 hot-swap with only two levels of staging.

Table 7-8 • Hot-Swap Level 1

Description	Cold-swap
Power Applied to Device	No
Bus State	–
Card Ground Connection	–
Device Circuitry Connected to Bus Pins	–
Example Application	System and card with Actel FPGA chip are powered down, and the card is plugged into the system. Then the power supplies are turned on for the system but not for the FPGA on the card.
Compliance of nano Devices	Compliant

Table 7-9 • Hot-Swap Level 2

Description	Hot-swap while reset
Power Applied to Device	Yes
Bus State	Held in reset state
Card Ground Connection	Reset must be maintained for 1 ms before, during, and after insertion/removal.
Device Circuitry Connected to Bus Pins	–
Example Application	In the PCI hot-plug specification, reset control circuitry isolates the card busses until the card supplies are at their nominal operating levels and stable.
Compliance of nano Devices	Compliant

Table 7-10 • Hot-Swap Level 3

Description	Hot-swap while bus idle
Power Applied to Device	Yes
Bus State	Held idle (no ongoing I/O processes during insertion/removal)
Card Ground Connection	Reset must be maintained for 1 ms before, during, and after insertion/removal.
Device Circuitry Connected to Bus Pins	Must remain glitch-free during power-up or power-down
Example Application	Board bus shared with card bus is "frozen," and there is no toggling activity on the bus. It is critical that the logic states set on the bus signal not be disturbed during card insertion/removal.
Compliance of nano Devices	Compliant

Table 7-11 • Hot-Swap Level 4

Description	Hot-swap on an active bus
Power Applied to Device	Yes
Bus State	Bus may have active I/O processes ongoing, but device being inserted or removed must be idle.
Card Ground Connection	Reset must be maintained for 1 ms before, during, and after insertion/removal.
Device Circuitry Connected to Bus Pins	Must remain glitch-free during power-up or power-down
Example Application	There is activity on the system bus, and it is critical that the logic states set on the bus signal not be disturbed during card insertion/removal.
Compliance of nano Devices	Compliant

For Level 3 and Level 4 compliance with the nano devices, cards with two levels of staging should have the following sequence:

- Grounds
- Powers, I/Os, and other pins

Cold-Sparing Support

Cold-sparing refers to the ability of a device to leave system data undisturbed when the system is powered up, while the component itself is powered down, or when power supplies are floating.

Cold-sparing is supported on all IGLOO nano and ProASIC3 nano devices only when the user provides resistors from each power supply to ground. The resistor value is calculated based on the decoupling capacitance on a given power supply. The RC constant should be greater than 3 μ s.

To remove resistor current during operation, it is suggested that the resistor be disconnected (e.g., with an NMOS switch) from the power supply after the supply has reached its final value. Refer to the *Power-Up/Down Behavior of Low-Power Flash Devices* chapter of the *ProASIC3* and *ProASIC3E* handbooks for details on cold-sparing.

Cold-sparing means that a subsystem with no power applied (usually a circuit board) is electrically connected to the system that is in operation. This means that all input buffers of the subsystem must present very high input impedance with no power applied so as not to disturb the operating portion of the system.

When targeting low-power applications, I/O cold-sparing may add additional current if a pin is configured with either a pull-up or pull-down resistor and driven in the opposite direction. A small static current is induced on each I/O pin when the pin is driven to a voltage opposite to the weak pull resistor. The current is equal to the voltage drop across the input pin divided by the pull resistor. Refer to the "Detailed I/O DC Characteristics" section of the appropriate family datasheet for the specific pull resistor value for the corresponding I/O standard.

For example, assuming an LVTTTL 3.3 V input pin is configured with a weak pull-up resistor, a current will flow through the pull-up resistor if the input pin is driven LOW. For LVTTTL 3.3 V, the pull-up resistor is ~ 45 k Ω , and the resulting current is equal to 3.3 V / 45 k Ω = 73 μ A when the I/O pin is driven LOW. This is true also when a weak pull-down is chosen and the input pin is driven HIGH. This current can be avoided by driving the input LOW when a weak pull-down resistor is used and driving it HIGH when a weak pull-up resistor is used.

This current draw can occur in the following cases:

- In Active and Static modes:
 - Input buffers with pull-up, driven LOW
 - Input buffers with pull-down, driven HIGH
 - Bidirectional buffers with pull-up, driven LOW
 - Bidirectional buffers with pull-down, driven HIGH
 - Output buffers with pull-up, driven LOW
 - Output buffers with pull-down, driven HIGH
 - Tristate buffers with pull-up, driven LOW
 - Tristate buffers with pull-down, driven HIGH
- In Flash*Freeze mode (not supported on ProASIC3 nano devices):
 - Input buffers with pull-up, driven LOW
 - Input buffers with pull-down, driven HIGH
 - Bidirectional buffers with pull-up, driven LOW
 - Bidirectional buffers with pull-down, driven HIGH

Electrostatic Discharge Protection

Low-power flash devices are tested per JEDEC Standard JESD22-A114-B.

These devices contain clamp diodes at every I/O, global, and power pad. Clamp diodes protect all device pads against damage from ESD as well as from excessive voltage transients.

All nano devices are qualified to the Human Body Model (HBM) and the Charged Device Model (CDM).

Table 7-12 • I/O Hot-Swap and 5 V Input Tolerance Capabilities in nano Devices

I/O Assignment	Clamp Diode	Hot Insertion	5 V Input Tolerance	Input Buffer	Output Buffer
3.3 V LVTTTL/LVCMOS	No	Yes	Yes*	Enabled/Disabled	
LVCMOS 2.5 V	No	Yes	No	Enabled/Disabled	
LVCMOS 1.8 V	No	Yes	No	Enabled/Disabled	
LVCMOS 1.5 V	No	Yes	No	Enabled/Disabled	
LVCMOS 1.2 V	No	Yes	No	Enabled/Disabled	

* Can be implemented with an external IDT bus switch, resistor divider, or Zener with resistor.

5 V Input and Output Tolerance

nano devices can be made 5 V–input–tolerant for certain I/O standards by using external level shifting techniques. 5 V output compliance can be achieved using certain I/O standards.

Table 7-5 on page 7-5 shows the I/O standards that support 5 V input tolerance. Only 3.3 V LVTTTL/LVCMOS standards support 5 V output tolerance.

5 V Input Tolerance

I/Os can support 5 V input tolerance when LVTTTL 3.3 V, LVCMOS 3.3 V, LVCMOS 2.5 V, LVCMOS 1.8 V, LVCMOS 1.5 V, and LVCMOS 1.2 V configurations are used (see Table 7-12). There are three recommended solutions for achieving 5 V receiver tolerance (see Figure 7-5 on page 7-14 to Figure 7-7 on page 7-15 for details of board and macro setups). All the solutions meet a common requirement of limiting the voltage at the input to 3.6 V or less. In fact, the I/O absolute maximum voltage rating is 3.6 V, and any voltage above 3.6 V may cause long-term gate oxide failures.

Solution 1

The board-level design must ensure that the reflected waveform at the pad does not exceed the limits provided in the recommended operating conditions in the datasheet. This is a requirement to ensure long-term reliability.

This solution requires two board resistors, as demonstrated in Figure 7-5 on page 7-14. Here are some examples of possible resistor values (based on a simplified simulation model with no line effects and 10 Ω transmitter output resistance, where $R_{tx_out_high} = (V_{CC1} - V_{OH}) / I_{OH}$ and $R_{tx_out_low} = V_{OL} / I_{OL}$).

Example 1 (high speed, high current):

$$R_{tx_out_high} = R_{tx_out_low} = 10 \Omega$$

$$R1 = 36 \Omega (\pm 5\%), P(r1)_{min} = 0.069 \Omega$$

$$R2 = 82 \Omega (\pm 5\%), P(r2)_{min} = 0.158 \Omega$$

$$I_{max_tx} = 5.5 \text{ V} / (82 \times 0.95 + 36 \times 0.95 + 10) = 45.04 \text{ mA}$$

$$t_{RISE} = t_{FALL} = 0.85 \text{ ns at } C_{pad_load} = 10 \text{ pF (includes up to 25\% safety margin)}$$

$$t_{RISE} = t_{FALL} = 4 \text{ ns at } C_{pad_load} = 50 \text{ pF (includes up to 25\% safety margin)}$$

Example 2 (low-medium speed, medium current):

$$R_{tx_out_high} = R_{tx_out_low} = 10 \, \Omega$$

$$R1 = 220 \, \Omega (\pm 5\%), P(r1)_{min} = 0.018 \, \Omega$$

$$R2 = 390 \, \Omega (\pm 5\%), P(r2)_{min} = 0.032 \, \Omega$$

$$I_{max_tx} = 5.5 \, V / (220 \times 0.95 + 390 \times 0.95 + 10) = 9.17 \, mA$$

$$t_{RISE} = t_{FALL} = 4 \, ns \text{ at } C_{pad_load} = 10 \, pF \text{ (includes up to 25\% safety margin)}$$

$$t_{RISE} = t_{FALL} = 20 \, ns \text{ at } C_{pad_load} = 50 \, pF \text{ (includes up to 25\% safety margin)}$$

Other values of resistors are also allowed as long as the resistors are sized appropriately to limit the voltage at the receiving end to $2.5 \, V < V_{in} (rx) < 3.6 \, V$ when the transmitter sends a logic 1. This range of $V_{in_dc}(rx)$ must be assured for any combination of transmitter supply ($5 \, V \pm 0.5 \, V$), transmitter output resistance, and board resistor tolerances.

Temporary overshoots are allowed according to the overshoot and undershoot table in the datasheet.

Solution 1

Figure 7-5 • Solution 1

Solution 2

This solution requires one board resistor and one Zener 3.3 V diode, as demonstrated in Figure 7-6.

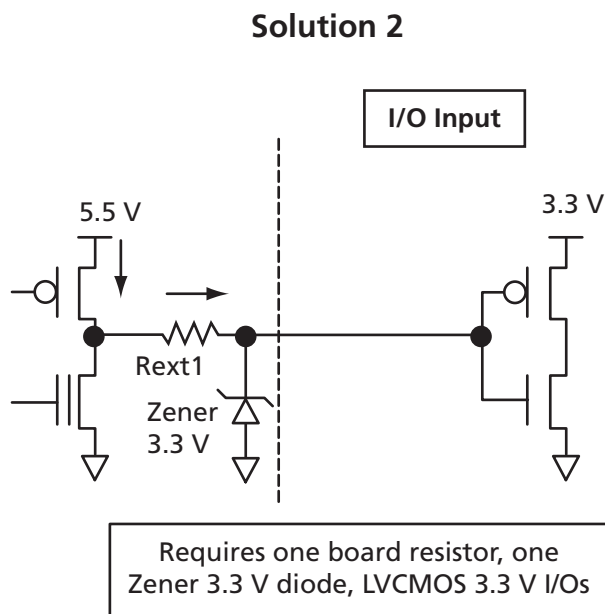

Figure 7-6 • Solution 2

Solution 3

This solution requires a bus switch on the board, as demonstrated in Figure 7-7.

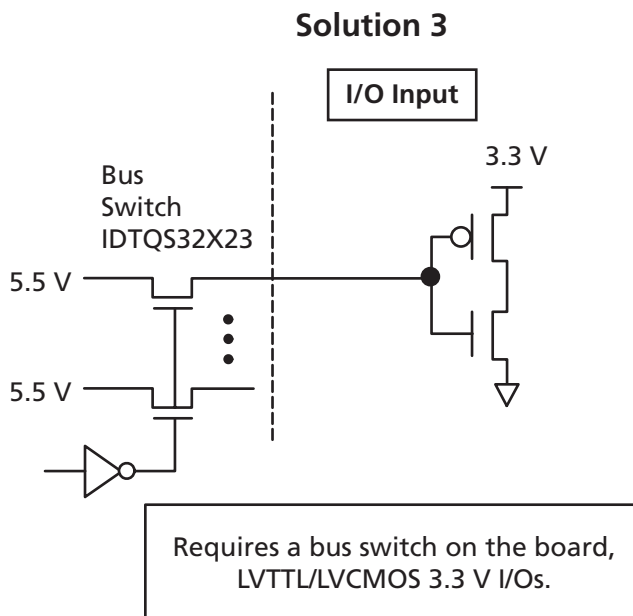

Figure 7-7 • Solution 3

Table 7-13 • Comparison Table for 5 V–Compliant Receiver Solutions

Solution	Board Components	Speed	Current Limitations
1	Two resistors	Low to High ¹	Limited by transmitter's drive strength
2	Resistor and Zener 3.3 V	Medium	Limited by transmitter's drive strength
3	Bus switch	High	N/A

Notes:

1. Speed and current consumption increase as the board resistance values decrease.
2. Resistor values ensure I/O diode long-term reliability.
3. At 70°C, customers could still use 420 Ω on every I/O.
4. At 85°C, a 5 V solution on every other I/O is permitted, since the resistance is lower (150 Ω) and the current is higher. Also, the designer can still use 420 Ω and use the solution on every I/O.
5. At 100°C, the 5 V solution on every I/O is permitted, since 420 Ω are used to limit the current to 5.9 mA.

5 V Output Tolerance

nano Standard I/Os must be set to 3.3 V LVTTTL or 3.3 V LVCMOS mode to reliably drive 5 V TTL receivers. It is also critical that there be NO external I/O pull-up resistor to 5 V, since this resistor would pull the I/O pad voltage beyond the 3.6 V absolute maximum value and consequently cause damage to the I/O.

When set to 3.3 V LVTTTL or 3.3 V LVCMOS mode, the I/Os can directly drive signals into 5 V TTL receivers. In fact, $V_{OL} = 0.4$ V and $V_{OH} = 2.4$ V in both 3.3 V LVTTTL and 3.3 V LVCMOS modes exceeds the $V_{IL} = 0.8$ V and $V_{IH} = 2$ V level requirements of 5 V TTL receivers. Therefore, level 1 and level 0 will be recognized correctly by 5 V TTL receivers.

Schmitt Trigger

A Schmitt trigger is a buffer used to convert a slow or noisy input signal into a clean one before passing it to the FPGA. Using Schmitt trigger buffers guarantees a fast, noise-free input signal to the FPGA.

nano devices have Schmitt triggers built into their I/O circuitry. Schmitt Trigger is available on all I/O configurations.

This feature can be implemented by using a Physical Design Constraints (PDC) command (Table 7-5 on page 7-5) or by selecting a check box in the I/O Attribute Editor in Designer. The check box is cleared by default.

I/O Register Combining

Every I/O has several embedded registers in the I/O tile that are close to the I/O pads. Rather than using the internal register from the core, the user has the option of using these registers for faster clock-to-out timing, and external hold and setup. When combining these registers at the I/O buffer, some architectural rules must be met. Provided these rules are met, the user can enable register combining globally during Compile (as shown in the "Compiling the Design" section in the *I/O Software Control in Low-Power Flash Devices* section of the handbook).

This feature is supported by all I/O standards.

Rules for Registered I/O Function:

1. The fanout between an I/O pin (D, Y, or E) and a register must be equal to one for combining to be considered on that pin.
2. All registers (Input, Output, and Output Enable) connected to an I/O must share the same clear or preset function:
 - If one of the registers has a CLR pin, all the other registers that are candidates for combining in the I/O must have a CLR pin.

- If one of the registers has a PRE pin, all the other registers that are candidates for combining in the I/O must have a PRE pin.
 - If one of the registers has neither a CLR nor a PRE pin, all the other registers that are candidates for combining must have neither a CLR nor a PRE pin.
 - If the clear or preset pins are present, they must have the same polarity.
 - If the clear or preset pins are present, they must be driven by the same signal (net).
3. For single-tile devices (10 k, 15 k, and 20 k): Registers connected to an I/O on the Output and Output Enable pins must have the same clock function (both CLR and CLK are shared among all registers):
 - Both the Output and Output Enable registers must not have an E pin (clock enable).
 4. For dual-tile devices (60 k, 125 k, and 250 k): Registers connected to an I/O on the Output and Output Enable pins must have the same clock and enable function:
 - Both the Output and Output Enable registers must have an E pin (clock enable), or none at all.
 - If the E pins are present, they must have the same polarity. The CLK pins must also have the same polarity.

In some cases, the user may want registers to be combined with the input of a bibuf while maintaining the output as-is. This can be achieved by using PDC commands as follows:

```
set_io <signal name> -REGISTER yes -----register will combine
set_preserve <signal name> ----register will not combine
```

Weak Pull-Up and Weak Pull-Down Resistors

nano devices support optional weak pull-up and pull-down resistors on each I/O pin. When the I/O is pulled up, it is connected to the V_{CCI} of its corresponding I/O bank. When it is pulled down, it is connected to GND. Refer to the datasheet for more information.

For low-power applications and when using IGLOO nano devices, configuration of the pull-up or pull-down of the I/O can be used to set the I/O to a known state while the device is in Flash*Freeze mode. Refer to *Flash*Freeze Technology and Low-Power Modes in IGLOO and ProASIC3L Devices* for more information.

The Flash*Freeze (FF) pin cannot be configured with a weak pull-down or pull-up I/O attribute, as the signal needs to be driven at all times.

Output Slew Rate Control

The slew rate is the amount of time an input signal takes to get from logic LOW to logic HIGH or vice versa.

It is commonly defined as the propagation delay between 10% and 90% of the signal's voltage swing. Slew rate control is available for the output buffers of low-power flash devices. The output buffer has a programmable slew rate for both HIGH-to-LOW and LOW-to-HIGH transitions.

The slew rate can be implemented by using a PDC command (Table 7-5 on page 7-5), setting it "High" or "Low" in the I/O Attribute Editor in Designer, or instantiating a special I/O macro. The default slew rate value is "High."

Actel recommends the high slew rate option to minimize the propagation delay. This high-speed option may introduce noise into the system if appropriate signal integrity measures are not adopted. Selecting a low slew rate reduces this kind of noise but adds some delays in the system. Low slew rate is recommended when bus transients are expected.

Output Drive

The output buffers of nano devices can provide multiple drive strengths to meet signal integrity requirements. The LVTTTL and LVCMOS (except 1.2 V LVCMOS) standards have selectable drive strengths.

Drive strength should also be selected according to the design requirements and noise immunity of the system.

Refer to [Table 7-10 on page 7-11](#) for more information about the slew rate and drive strength specification for LVTTTL/LVCMOS 3.3 V, LVCMOS 2.5 V, LVCMOS 1.8 V, LVCMOS 1.5 V, and LVCMOS 1.2 V output buffers.

Table 7-14 • nano Output Drive and Slew

I/O Standards	2 mA	4 mA	6 mA	8 mA	Slew	
LVTTTL / LVCMOS 3.3 V	✓	✓	✓	✓	High	Low
LVCMOS 2.5 V	✓	✓	✓	✓	High	Low
LVCMOS 1.8 V	✓	✓	–	–	High	Low
LVCMOS 1.5 V	✓	–	–	–	High	Low
LVCMOS 1.2 V	✓	–	–	–	High	Low

Simultaneously Switching Outputs (SSOs) and Printed Circuit Board Layout

Each I/O voltage bank has a separate ground and power plane for input and output circuits. This isolation is necessary to minimize simultaneous switching noise from the input and output (SSI and SSO). The switching noise (ground bounce and power bounce) is generated by the output buffers and transferred into input buffer circuits, and vice versa.

SSOs can cause signal integrity problems on adjacent signals that are not part of the SSO bus. Both inductive and capacitive coupling parasitics of bond wires inside packages and of traces on PCBs will transfer noise from SSO busses onto signals adjacent to those busses. Additionally, SSOs can produce ground bounce noise and V_{CC1} dip noise. These two noise types are caused by rapidly changing currents through GND and V_{CC1} package pin inductances during switching activities ([EQ 7-1](#) and [EQ 7-2](#)).

$$\text{Ground bounce noise voltage} = L(\text{GND}) \times di/dt$$

EQ 7-1

$$V_{CC1} \text{ dip noise voltage} = L(V_{CC1}) \times di/dt$$

EQ 7-2

Any group of four or more input pins switching on the same clock edge is considered an SSO bus. The shielding should be done both on the board and inside the package unless otherwise described.

In-package shielding can be achieved in several ways; the required shielding will vary depending on whether pins next to the SSO bus are LVTTTL/LVCMOS inputs or LVTTTL/LVCMOS outputs. Board traces in the vicinity of the SSO bus have to be adequately shielded from mutual coupling and inductive noise that can be generated by the SSO bus. Also, noise generated by the SSO bus needs to be reduced inside the package.

PCBs perform an important function in feeding stable supply voltages to the IC and, at the same time, maintaining signal integrity between devices.

Key issues that need to be considered are as follows:

- Power and ground plane design and decoupling network design
- Transmission line reflections and terminations

For extensive data per package on the SSO and PCB issues, refer to [ProASIC3/E SSO and Pin Placement and Guidelines](#) chapter of the handbook.

I/O Software Support

In Actel's Libero IDE software, default settings have been defined for the various I/O standards supported. Changes can be made to the default settings via the use of attributes; however, not all I/O attributes are applicable for all I/O standards.

Table 7-15 • nano I/O Attributes vs. I/O Standard Applications

I/O Standard	SLEW (output only)	OUT_DRIVE (output only)	RES_PULL	OUT_LOAD (output only)		Schmitt Trigger	Hold State	Combine Register
				IGLOO nano	ProASIC3 nano			
LVTTTL/ LVCMOS3.3	✓	✓ (8)	✓	✓	✓	✓	✓	✓
LVCMOS2.5	✓	✓ (8)	✓	✓	✓	✓	✓	✓
LVCMOS1.8	✓	✓ (4)	✓	✓	✓	✓	✓	✓
LVCMOS1.5	✓	✓ (2)	✓	✓	✓	✓	✓	✓
LVCMOS1.2	✓	✓ (2)	✓	✓	–	✓	✓	✓
Software Defaults	HIGH	Refer to numbers in parentheses in above cells.	None	All Devices: 5 pF	10 pF or 35 pF*	Off	Off	No

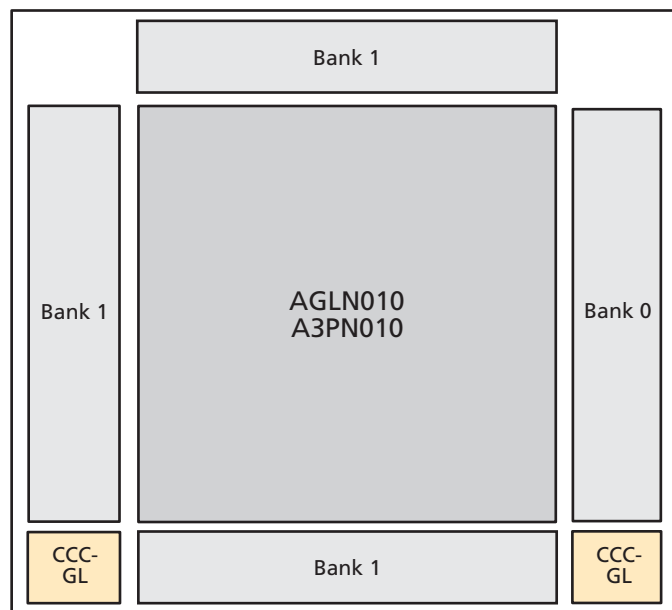

Note: *10 pF for A3PN010, A3PN015, and A3PN020; 35 pF for A3PN060, A3PN125, and A3PN250.

I/O Bank Architecture and CCC Naming Conventions

The nano products feature varying bank architectures which have been optimized to balance silicon area with I/O and clocking flexibility. The A standard naming scheme is used to illustrate the I/O Bank architecture and the CCCs associated with each architecture.

Table 7-16 • A Standard Naming Scheme

Name	Description
Bank x	Refers to the specific bank number within which an I/O resides
CCC	Clock Condition Circuit with simple clock delay operations as well as clock spine access
CCC-GL	Clock Condition Circuit with Global Locations for chip reach clocking. These CCCs support programmable delays but do not have an integrated PLL.
CCC-PLL	Clock Condition Circuit with integrated PLL and programmable delays
Chip Reach	Access to chip global lines
Quadrant Reach	Access to quadrant global lines

Legend

Chip Reach
 CCC-GL = CCC with no PLL
 (does not support programmable delays)

Board-Level Considerations

Low-power flash devices have robust I/O features that can help in reducing board-level components. The devices offer single-chip solutions, which makes the board layout simpler and more immune to signal integrity issues. Although, in many cases, these devices resolve board-level issues, special attention should always be given to overall signal integrity. This section covers important board-level considerations to facilitate optimum device performance.

Termination

Proper termination of all signals is essential for good signal quality. Nonterminated signals, especially clock signals, can cause malfunctioning of the device.

For general termination guidelines, refer to the *Board-Level Considerations* application note for Actel FPGAs. Also refer to *Pin Descriptions* for termination requirements for specific pins.

Low-power flash I/Os are equipped with on-chip pull-up/-down resistors. The user can enable these resistors by instantiating them either in the top level of the design (refer to the *IGLOO, Fusion, and ProASIC3 Macro Library Guide* for the available I/O macros with pull-up/-down) or in the I/O Attribute Editor in Designer if generic input or output buffers are instantiated in the top level. Unused I/O pins are configured as inputs with pull-up resistors.

As mentioned earlier, low-power flash devices have multiple programmable drive strengths, and the user can eliminate unwanted overshoot and undershoot by adjusting the drive strengths.

Power-Up Behavior

Low-power flash devices are power-up/-down friendly; i.e., no particular sequencing is required for power-up and power-down. This eliminates extra board components for power-up sequencing, such as a power-up sequencer.

During power-up, all I/Os are tristated, irrespective of I/O macro type (input buffers, output buffers, I/O buffers with weak pull-ups or weak pull-downs, etc.). Once I/Os become activated, they are set to the user-selected I/O macros. Refer to the *Power-Up/Down Behavior of Low-Power Flash Devices* chapter of the *ProASIC3* and *ProASIC3E* handbooks for details.

Drive Strength

Low-power flash devices have up to four programmable output drive strengths. The user can select the drive strength of a particular output in the I/O Attribute Editor or can instantiate a specialized I/O macro, such as OUTBUF_S_8 (slew = low, out_drive = 8 mA).

The maximum available drive strength is 8 mA per I/O. Though no I/O should be forced to source or sink more than 8 mA indefinitely, I/Os may handle a higher amount of current (refer to the device IBIS model for maximum source/sink current) during signal transition (AC current). Every device package has its own power dissipation limit; hence, power calculation must be performed accurately to determine how much current can be tolerated per I/O within that limit.

I/O Interfacing

Low-power flash devices are 5 V–input– and 5 V–output–tolerant without adding any extra circuitry. Along with other low-voltage I/O macros, this 5 V tolerance makes these devices suitable for many types of board component interfacing.

Table 7-17 shows some high-level interfacing examples using low-power flash devices.

Table 7-17 • nano High-Level Interface

Interface	Clock		I/O			
	Type	Frequency	Type	Signals In	Signals Out	Data I/O
GM	Src Sync	125 MHz	LVTTL	8	8	125 Mbps
TBI	Src Sync	125 MHz	LVTTL	10	10	125 Mbps

Conclusion

IGLOO nano and ProASIC3 nano device support for multiple I/O standards minimizes board-level components and makes possible a wide variety of applications. The Actel Designer software, integrated with Actel Libero IDE, presents a clear visual display of I/O assignments, allowing users to verify I/O and board-level design requirements before programming the device. The nano device I/O features and functionalities ensure board designers can produce low-cost and low-power FPGA applications fulfilling the complexities of contemporary design needs.

Revised December 2008

8 – I/O Software Control in Low-Power Flash Devices

Actel Fusion,® IGLOO,® and ProASIC®3 I/Os provide more design flexibility, allowing the user to control specific features by enabling certain I/O standards. Some features are selectable only for certain I/O standards, whereas others are available for all I/O standards. For example, slew control is not supported by differential I/O standards. Conversely, I/O register combining is supported by all I/O standards. For detailed information about which I/O standards and features are available on each device and each I/O type, refer to the I/O Structures section of the handbook for the device you are using.

Figure 8-1 shows the various points in the software design flow where a user can provide input or control of the I/O selection and parameters. A detailed description is provided throughout this document.

Figure 8-1 • User I/O Assignment Flow Chart

Flash FPGAs I/O Support

The flash FPGAs listed in [Table 8-1](#) support I/Os and the functions described in this document.

Table 8-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 8-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 8-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Software-Controlled I/O Attributes

Users may modify these programmable I/O attributes using the I/O Attribute Editor. Modifying an I/O attribute may result in a change of state in Designer. Table 8-2 details which steps have to be re-run as a function of modified I/O attribute.

Table 8-2 • Designer State (resulting from I/O attribute modification)

I/O Attribute	Designer States				
	Compile	Layout	Fuse	Timing	Power
Slew Control	No	No	Yes	Yes	Yes
Output Drive (mA)	No	No	Yes	Yes	Yes
Skew Control	No	No	Yes	Yes	Yes
Resistor Pull	No	No	Yes	Yes	Yes
Input Delay	No	No	Yes	Yes	Yes
Schmitt Trigger	No	No	Yes	Yes	Yes
OUT_LOAD	No	No	No	Yes	Yes
COMBINE_REGISTER	Yes	Yes	N/A	N/A	N/A

Notes:

1. No = Remains the same, Yes = Re-run the step, N/A = Not applicable
2. Skew control and input delay do not apply to IGLOO nano, IGLOO PLUS, and ProASIC3 nano devices.

Implementing I/Os in Actel Software

Actel Libero® Integrated Design Environment (IDE) is integrated with design entry tools such as the SmartGen macro builder, the ViewDraw schematic entry tool, and an HDL editor. It is also integrated with the synthesis and Designer tools. In this section, all necessary steps to implement the I/Os are discussed.

Design Entry

There are three ways to implement I/Os in a design:

1. Use the SmartGen macro builder to configure I/Os by generating specific I/O library macros and then instantiating them in top-level code. This is especially useful when creating I/O bus structures.
2. Use an I/O buffer cell in a schematic design.
3. Manually instantiate specific I/O macros in the top-level code.

If technology-specific macros, such as INBUF_LVCMOS33 and OUTBUF_PCI, are used in the HDL code or schematic, the user will not be able to change the I/O standard later on in Designer. If generic I/O macros are used, such as INBUF, OUTBUF, TRIBUF, CLKBUF, and BIBUF, the user can change the I/O standard using the Designer I/O Attribute Editor tool.

Using SmartGen for I/O Configuration

The SmartGen tool in Libero IDE provides a GUI-based method of configuring the I/O attributes. The user can select certain I/O attributes while configuring the I/O macro in SmartGen. The steps to configure an I/O macro with specific I/O attributes are as follows:

1. Open Libero IDE.
2. On the left-hand side of the Catalog View, select I/O, as shown in Figure 8-2.

Figure 8-2 • SmartGen Catalog

- Expand the I/O section and double-click one of the options (Figure 8-3).

Figure 8-3 • Expanded I/O Section

- Double-click any of the varieties. The I/O Create Core window opens (Figure 8-4).

Figure 8-4 • I/O Create Core Window

As seen in Figure 8-4, there are five tabs to configure the I/O macro: Input Buffers, Output Buffers, Bidirectional Buffers, Tristate Buffers, and DDR.

Input Buffers

There are two variations: Regular and Special.

If the **Regular** variation is selected, only the Width (1 to 128) needs to be entered. The default value for Width is 1.

The **Special** variation has Width, Technology, Voltage Level, and Resistor Pull-Up/Down options (see Figure 8-4). All the I/O standards and supply voltages (V_{CC}) supported for the device family are available for selection.

Output Buffers

There are two variations: Regular and Special.

If the **Regular** variation is selected, only the Width (1 to 128) needs to be entered. The default value for Width is 1.

The **Special** variation has Width, Technology, Output Drive, and Slew Rate options.

Bidirectional Buffers

There are two variations: Regular and Special.

The **Regular** variation has Enable Polarity (Active High, Active Low) in addition to the Width option.

The **Special** variation has Width, Technology, Output Drive, Slew Rate, and Resistor Pull-Up/Down options.

Tristate Buffers

Same as Bidirectional Buffers.

DDR

There are eight variations: DDR with Regular Input Buffers, Special Input Buffers, Regular Output Buffers, Special Output Buffers, Regular Tristate Buffers, Special Tristate Buffers, Regular Bidirectional Buffers, and Special Bidirectional Buffers.

These variations resemble the options of the previous I/O macro. For example, the Special Input Buffers variation has Width, Technology, Voltage Level, and Resistor Pull-Up/Down options. DDR is not available on IGLOO PLUS devices.

5. Once the desired configuration is selected, click the **Generate** button. The Generate Core window opens (Figure 8-5).
6. Enter a name for the macro. Click **OK**. The core will be generated and saved to the appropriate location within the project files (Figure 8-6 on page 8-7).

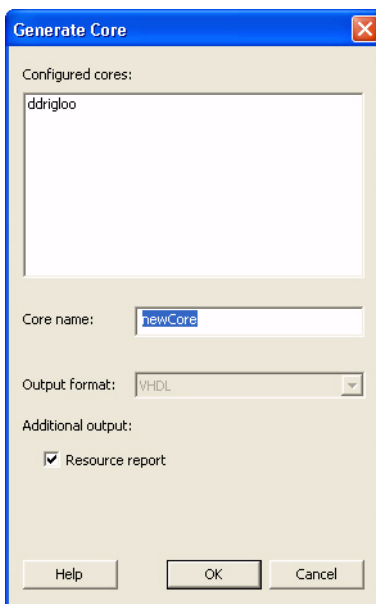

Figure 8-5 • Generate Core Window

7. Instantiate the I/O macro in the top-level code.
The user must instantiate the DDR_REG or DDR_OUT macro in the design. Use SmartGen to generate both these macros and then instantiate them in your top level. To combine the DDR macros with the I/O, the following rules must be met:

Rules for the DDR I/O Function

- The fanout between an I/O pin (D or Y) and a DDR (DDR_REG or DDR_OUT) macro must be equal to one for the combining to happen on that pin.
- If a DDR_REG macro and a DDR_OUT macro are combined on the same bidirectional I/O, they must share the same clear signal.
- Registers will not be combined in an I/O in the presence of DDR combining on the same I/O.

Using the I/O Buffer Schematic Cell

Libero IDE includes the ViewDraw schematic entry tool. Using ViewDraw, the user can insert any supported I/O buffer cell in the top-level schematic. Figure 8-6 shows a top-level schematic with different I/O buffer cells. When synthesized, the netlist will contain the same I/O macro.

Figure 8-6 • I/O Buffer Schematic Cell Usage

Instantiating in HDL code

All the supported I/O macros can be instantiated in the top-level HDL code (refer to the *IGLOO, Fusion, and ProASIC3 Macro Library Guide* for a detailed list of all I/O macros). The following is an example:

```
library ieee;
use ieee.std_logic_1164.all;
library proasic3e;

entity TOP is
  port(IN2, IN1 : in std_logic; OUT1 : out std_logic);
end TOP;

architecture DEF_ARCH of TOP is

  component INBUF_LVCMOS5U
    port(PAD : in std_logic := 'U'; Y : out std_logic);
  end component;

  component INBUF_LVCMOS5
    port(PAD : in std_logic := 'U'; Y : out std_logic);
  end component;

  component OUTBUF_SSTL3_II
    port(D : in std_logic := 'U'; PAD : out std_logic);
  end component;

  Other component ....

  signal x, y, z.....other signals : std_logic;

begin

  I1 : INBUF_LVCMOS5U
    port map(PAD => IN1, Y =>x);
  I2 : INBUF_LVCMOS5
    port map(PAD => IN2, Y => y);
  I3 : OUTBUF_SSTL3_II
    port map(D => z, PAD => OUT1);

  other port mapping...

end DEF_ARCH;
```

Synthesizing the Design

Libero IDE integrates with the Synplify® synthesis tool. Other synthesis tools can also be used with Libero IDE. Refer to the *Actel Libero IDE User's Guide* or Libero IDE online help for details on how to set up the Libero IDE tool profile with synthesis tools from other vendors.

During synthesis, the following rules apply:

- Generic macros:
 - Users can instantiate generic INBUF, OUTBUF, TRIBUF, and BIBUF macros.
 - Synthesis will automatically infer generic I/O macros.
 - The default I/O technology for these macros is LVTTTL.
 - Users will need to use the I/O Attribute Editor in Designer to change the default I/O standard if needed (see [Figure 8-7 on page 8-9](#)).
- Technology-specific I/O macros:
 - Technology-specific I/O macros, such as INBUF_LVCMO25 and OUTBUF_GTL25, can be instantiated in the design. Synthesis will infer these I/O macros in the netlist.

- The I/O standard of technology-specific I/O macros cannot be changed in the I/O Attribute Editor (see Figure 8-7).
- The user MUST instantiate differential I/O macros (LVDS/LVPECL) in the design. This is the only way to use these standards in the design.
- To implement the DDR I/O function, the user must instantiate a DDR_REG or DDR_OUT macro. This is the only way to use a DDR macro in the design.

Figure 8-7 • Assigning a Different I/O Standard to the Generic I/O Macro

Performing Place-and-Route on the Design

The netlist created by the synthesis tool should now be imported into Designer and compiled. During Compile, the user can specify the I/O placement and attributes by importing the PDC file. The user can also specify the I/O placement and attributes using ChipPlanner and the I/O Attribute Editor under MVN.

Defining I/O Assignments in the PDC File

A PDC file is a Tcl script file specifying physical constraints. This file can be imported to and exported from Designer.

Table 8-3 shows I/O assignment constraints supported in the PDC file.

Table 8-3 • PDC I/O Constraints

Command	Action	Example	Comment
I/O Banks Setting Constraints			
set_iobank	Sets the I/O supply voltage, V_{CCI} , and the input reference voltage, V_{REF} for the specified I/O bank.	<pre>set_iobank bankname [-vcci vcci_voltage] [-vref vref_voltage] set_iobank Bank7 -vcci 1.50 -vref 0.75</pre>	Must use in case of mixed I/O voltage (V_{CCI}) design
set_vref	Assigns a V_{REF} pin to a bank.	<pre>set_vref -bank [bankname] [pinnum] set_vref -bank Bank0 685 704 723 742 761</pre>	Must use if voltage-referenced I/Os are used

Note: Refer to the Actel Libero IDE User's Guide for detailed rules on PDC naming and syntax conventions.

Table 8-3 • PDC I/O Constraints (continued)

Command	Action	Example	Comment
set_vref_defaults	Sets the default V_{REF} pins for the specified bank. This command is ignored if the bank does not need a V_{REF} pin.	set_vref_defaults bankname set_vref_defaults bank2	
I/O Attribute Constraint			
set_io	Sets the attributes of an I/O	set_io portname [-pinname value] [-fixed value] [-iostd value] [-out_drive value] [-slew value] [-res_pull value] [-schmitt_trigger value] [-in_delay value] [-skew value] [-out_load value] [-register value] set_io IN2 -pinname 28 -fixed yes -iostd LVCMOS15 -out_drive 12 -slew high -RES_PULL None -SCHMITT_TRIGGER Off -IN_DELAY Off -skew off -REGISTER No	If the I/O macro is generic (e.g., INBUF) or technology-specific (INBUF_LVCMOS25), then all I/O attributes can be assigned using this constraint. If the netlist has an I/O macro that specifies one of its attributes, that attribute cannot be changed using this constraint, though other attributes can be changed. Example: OUTBUF_S_24 (low slew, output drive 24 mA) Slew and output drive cannot be changed.
I/O Region Placement Constraints			
define_region	Defines either a rectangular region or a rectilinear region	define_region -name [region_name] -type [region_type] x1 y1 x2 y2 define_region -name test -type inclusive 0 15 2 29	If any number of I/Os must be assigned to a particular I/O region, such a region can be created with this constraint.
assign_region	Assigns a set of macros to a specified region	assign_region [region name] [macro_name...] assign_region test U12	This constraint assigns I/O macros to the I/O regions. When assigning an I/O macro, PDC naming conventions must be followed if the macro name contains special characters; e.g., if the macro name is <code>\\\$1119\\</code> , the correct use of escape characters is <code>\\\\\\\$1119\\\\\\</code> .

Note: Refer to the Actel Libero IDE User's Guide for detailed rules on PDC naming and syntax conventions.

Compiling the Design

During Compile, a PDC I/O constraint file can be imported along with the netlist file. If only the netlist file is compiled, certain I/O assignments need to be completed before proceeding to Layout. All constraints that can be entered in PDC can also be entered using ChipPlanner, I/O Attribute Editor, and PinEditor.

There are certain rules that must be followed in implementing I/O register combining and the I/O DDR macro (refer to the I/O Registers section of the handbook for the device that you are using and the "DDR" section on page 8-6 for details). Provided these rules are met, the user can enable or disable I/O register combining by using the PDC command `set_io portname -register yes|no` in the I/O Attribute Editor or selecting a check box in the Compile Options dialog box (see Figure 8-8). The Compile Options dialog box appears when the design is compiled for the first time. It can also be accessed by choosing **Options > Compile** during successive runs. I/O register combining is off by default. The PDC command overrides the setting in the Compile Options dialog box.

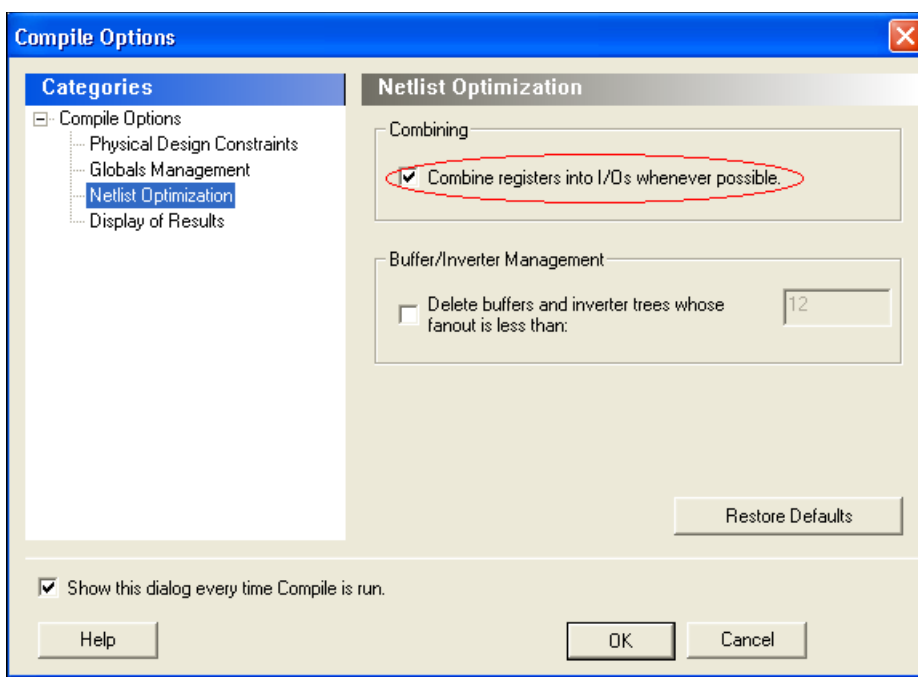

Figure 8-8 • Setting Register Combining During Compile

Understanding the Compile Report

The I/O bank report is generated during Compile and displayed in the log window. This report lists the I/O assignments necessary before Layout can proceed.

When Designer is started, the I/O Bank Assigner tool is run automatically if the Layout command is executed. The I/O Bank Assigner takes care of the necessary I/O assignments. However, these assignments can also be made manually with MVN or by importing the PDC file. Refer to the "Assigning Technologies and V_{REF} to I/O Banks" section on page 8-14 for further description.

The I/O bank report can also be extracted from Designer by choosing **Tools > Report** and setting the Report Type to **IOBank**.

This report has the following tables: I/O Function, I/O Technology, I/O Bank Resource Usage, and I/O Voltage Usage. This report is useful if the user wants to do I/O assignments manually.

I/O Function

Figure 8-9 shows an example of the I/O Function table included in the I/O bank report:

I/O Function:			
Type	w/o register	w/ register	w/ DDR register
Input I/O	7	0	1
Output I/O	1	1	0
Bidirectional I/O	0	0	0
Differential Input I/O Pairs	0	0	0
Differential Output I/O Pairs	0	0	1

Figure 8-9 • I/O Function Table

This table lists the number of input I/Os, output I/Os, bidirectional I/Os, and differential input and output I/O pairs that use I/O and DDR registers.

Certain rules must be met to implement registered and DDR I/O functions (refer to the I/O Structures section of the handbook for the device you are using and the "DDR" section on page 8-6).

I/O Technology

The I/O Technology table (shown in Figure 8-10) gives the values of V_{CCI} and V_{REF} (reference voltage) for all the I/O standards used in the design. The user should assign these voltages appropriately.

I/O Technology:					
I/O Standard(s)	Voltages		I/Os		
	Vcc1	Vref	Input	Output	Bidirectional
LVTTL	3.30v	N/A	1	1	0
LVCOS33	3.30v	N/A	1	0	0
LVCOS25_50	2.50v	N/A	1	1	0
LVCOS18	1.80v	N/A	1	0	0
LVCOS15	1.50v	N/A	1	0	0
PCIX	3.30v	N/A	1	0	0
LVDS	2.50v	N/A	0	2	0
SSTL3I (Input/Bidirectional)	3.30v	1.50v	1	0	0
GTLP33 (Input/Bidirectional)	3.30v	1.00v	1	0	0

Figure 8-10 • I/O Technology Table

I/O Bank Resource Usage

This is an important portion of the report. The user must meet the requirements stated in this table. Figure 8-11 shows the I/O Bank Resource Usage table included in the I/O bank report:

```

I/O Bank Resource Usage:

      | Voltages | Single I/Os | Diff I/O Pairs | Vref I/Os
      |-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
      | Vcci | Vref | Used | Total | Used | Total | Used | Total | Vref Pins
      |-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
Bank0 | N/A | N/A | 0 | 25 | 0 | 12 | N/A | N/A | N/A
Bank1 | N/A | N/A | 0 | 15 | 0 | 7 | N/A | N/A | N/A
Bank2 | N/A | N/A | 0 | 17 | 0 | 6 | N/A | N/A | N/A
Bank3 | N/A | N/A | 0 | 16 | 0 | 7 | N/A | N/A | N/A
Bank4 | N/A | N/A | 0 | 15 | 0 | 7 | N/A | N/A | N/A
Bank5 | N/A | N/A | 0 | 22 | 0 | 10 | N/A | N/A | N/A
Bank6 | N/A | N/A | 0 | 19 | 0 | 9 | N/A | N/A | N/A
Bank7 | N/A | N/A | 0 | 18 | 0 | 7 | N/A | N/A | N/A

Warning: IOPRL1: 8 I/O Bank(s) have not been assigned any voltages.
         The I/O modules located in these banks cannot be assigned any I/O macro.

```

Figure 8-11 • I/O Bank Resource Usage Table

The example in Figure 8-11 shows that none of the I/O macros is assigned to the bank because more than one V_{CCI} is detected.

I/O Voltage Usage

The I/O Voltage Usage table provides the number of V_{REF} (E devices only) and V_{CCI} assignments required in the design. If the user decides to make I/O assignments manually (PDC or MVN), the issues listed in this table must be resolved before proceeding to Layout. As stated earlier, V_{REF} assignments must be made if there are any voltage-referenced I/Os.

Figure 8-12 shows the I/O Voltage Usage table included in the I/O bank report.

```

I/O Voltage Usage:

      Voltages | I/Os
      |-----|-----|-----|-----|
      Vcci | Vref | Used | Total
      |-----|-----|-----|-----|
1.50v | N/A | 1* | 0
1.80v | N/A | 1* | 0
2.50v | N/A | 4* | 0
3.30v | N/A | 6* | 0
3.30v | 1.00v | 1* | 0
3.30v | 1.50v | 1* | 0

Warning: IOPRL3: This design has infeasible I/O voltage requirement(s),
         which are indicated with a '*' in the I/O Voltage Usage table.
         Please consider importing a Physical Design Constraint (PDC) file or
         use the MultiView Navigator (MVN) to resolve the design's voltage requirements
         before running Layout.

```

Figure 8-12 • I/O Voltage Usage Table

The table in Figure 8-12 indicates that there are two voltage-referenced I/Os used in the design. Even though both of the voltage-referenced I/O technologies have the same V_{CCI} voltage, their V_{REF} voltages are different. As a result, two I/O banks are needed to assign the V_{CCI} and V_{REF} voltages.

In addition, there are six single-ended I/Os used that have the same V_{CCI} voltage. Since two banks are already assigned with the same V_{CCI} voltage and there are enough unused bonded I/Os in those banks, the user does not need to assign the same V_{CCI} voltage to another bank. The user needs to assign the other three V_{CCI} voltages to three more banks.

Assigning Technologies and V_{REF} to I/O Banks

Low-power flash devices offer a wide variety of I/O standards, including voltage-referenced standards. Before proceeding to Layout, each bank must have the required V_{CCI} voltage assigned for the corresponding I/O technologies used for that bank. The voltage-referenced standards require the use of a reference voltage (V_{REF}). This assignment can be done manually or automatically. The following sections describe this in detail.

Manually Assigning Technologies to I/O Banks

The user can import the PDC at this point and resolve this requirement. The PDC command is `set_iobank [bank name] -vcci [vcci value]`

Another method is to use the I/O Bank Settings dialog box (MVN > Edit > I/O Bank Settings) to set up the V_{CCI} voltage for the bank (Figure 8-13).

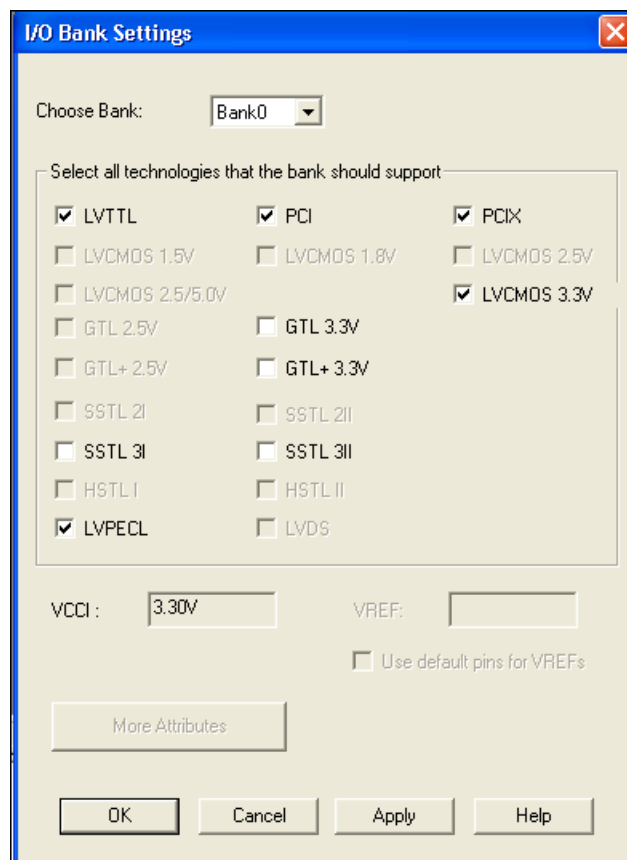

Figure 8-13 • Setting V_{CCI} for a Bank

The procedure is as follows:

1. Select the bank to which you want V_{CCI} to be assigned from the **Choose Bank** list.
2. Select the I/O standards for that bank. If you select any standard, the tool will automatically show all compatible standards that have a common V_{CCI} voltage requirement.
3. Click **Apply**.
4. Repeat steps 1–3 to assign V_{CCI} voltages to other banks. Refer to [Figure 8-12 on page 8-13](#) to find out how many I/O banks are needed for V_{CCI} bank assignment.

Manually Assigning V_{REF} Pins

Voltage-referenced inputs require an input reference voltage (V_{REF}). The user must assign V_{REF} pins before running Layout. Before assigning a V_{REF} pin, the user must set a V_{REF} technology for the bank to which the pin belongs.

V_{REF} Rules for the Implementation of Voltage-Referenced I/O Standards

The V_{REF} rules are as follows:

1. Any I/O (except JTAG I/Os) can be used as a V_{REF} pin.
2. One V_{REF} pin can support up to 15 I/Os. It is recommended, but not required, that eight of them be on one side and seven on the other side (in other words, all 15 can still be on one side of V_{REF}).
3. SSTL3 (I) and (II): Up to 40 I/Os per north or south bank in any position
4. LVPECL / GTL+ 3.3 V / GTL 3.3 V: Up to 48 I/Os per north or south bank in any position
5. SSTL2 (I) and (II) / GTL+ 2.5 V / GTL 2.5 V: Up to 72 I/Os per north or south bank in any position
6. V_{REF} minibanks partition rule: Each I/O bank is physically partitioned into V_{REF} minibanks. The V_{REF} pins within a V_{REF} minibank are interconnected internally, and consequently, only one V_{REF} voltage can be used within each V_{REF} minibank. If a bank does not require a V_{REF} signal, the V_{REF} pins of that bank are available as user I/Os.
7. The first V_{REF} minibank includes all I/Os starting from one end of the bank to the first power triple and eight more I/Os after the power triple. Therefore, the first V_{REF} minibank may contain (0 + 8), (2 + 8), (4 + 8), (6 + 8), or (8 + 8) I/Os.
The second V_{REF} minibank is adjacent to the first V_{REF} minibank and contains eight I/Os, a power triple, and eight more I/Os after the triple. An analogous rule applies to all other V_{REF} minibanks but the last.
The last V_{REF} minibank is adjacent to the previous one but contains eight I/Os, a power triple, and all I/Os left at the end of the bank. This bank may also contain (8 + 0), (8 + 2), (8 + 4), (8 + 6), or (8 + 8) available I/Os.

Example:

4 I/Os → Triple → 8 I/Os, 8 I/Os → Triple → 8 I/Os, 8 I/Os → Triple → 2 I/Os

That is, minibank A = (4 + 8) I/Os, minibank B = (8 + 8) I/Os, minibank C = (8 + 2) I/Os.

Assigning the V_{REF} Voltage to a Bank

When importing the PDC file, the V_{REF} voltage can be assigned to the I/O bank. The PDC command is as follows:

```
set_iobank -vref [value]
```

Another method for assigning V_{REF} is by using **MVN > Edit > I/O Bank Settings** ([Figure 8-14 on page 8-16](#)).

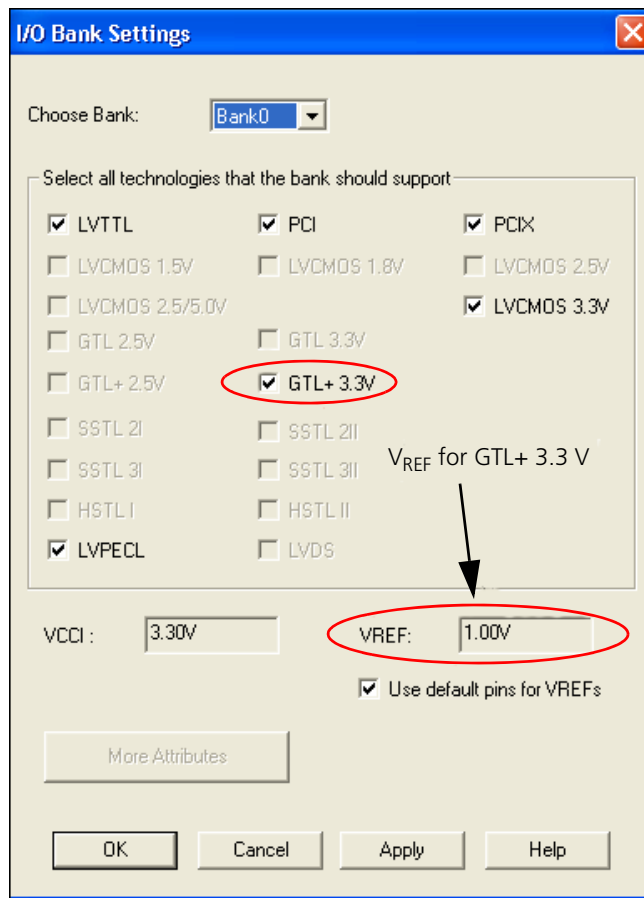

Figure 8-14 • Selecting V_{REF} Voltage for the I/O Bank

Assigning V_{REF} Pins for a Bank

The user can use default pins for V_{REF} . In this case, select the **Use default pins for VREFs** check box (Figure 8-14). This option guarantees full V_{REF} coverage of the bank. The equivalent PDC command is as follows:

```
set_vref_default [bank name]
```

To be able to choose V_{REF} pins, adequate V_{REF} pins must be created to allow legal placement of the compatible voltage-referenced I/Os.

To assign V_{REF} pins manually, the PDC command is as follows:

```
set_vref -bank [bank name] [package pin numbers]
```

For ChipPlanner/PinEditor to show the range of a V_{REF} pin, perform the following steps:

1. Assign V_{CC1} to a bank using **MVN > Edit > I/O Bank Settings**.
2. Open **ChipPlanner**. Zoom in on an I/O package pin in that bank.
3. Highlight the pin and then right-click. Choose **Use Pin for VREF**.

- Right-click and then choose **Highlight VREF range**. All the pins covered by that V_{REF} pin will be highlighted (Figure 8-15).

Figure 8-15 • V_{REF} Range

Using PinEditor or ChipPlanner, V_{REF} pins can also be assigned (Figure 8-16).

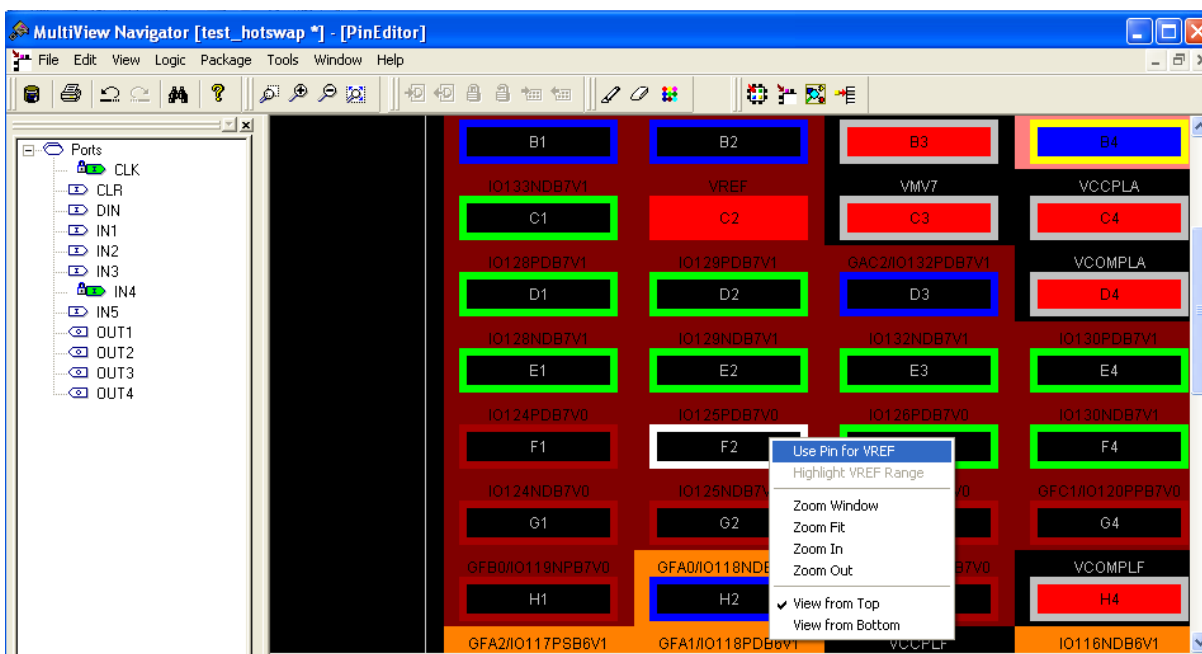

Figure 8-16 • Assigning V_{REF} from PinEditor

To unassign a V_{REF} pin:

- Select the pin to unassign.
- Right-click and choose **Use Pin for VREF**. The check mark next to the command disappears. The V_{REF} pin is now a regular pin.

Resetting the pin may result in unassigning I/O cores, even if they are locked. In this case, a warning message appears so you can cancel the operation.

After you assign the V_{REF} pins, right-click a V_{REF} pin and choose **Highlight VREF Range** to see how many I/Os are covered by that pin. To unhighlight the range, choose **Unhighlight All** from the **Edit** menu.

Automatically Assigning Technologies to I/O Banks

The I/O Bank Assigner (IOBA) tool runs automatically when you run Layout. You can also use this tool from within the MultiView Navigator (Figure 8-18). The IOBA tool automatically assigns technologies and V_{REF} pins (if required) to every I/O bank that does not currently have any technologies assigned to it. This tool is available when at least one I/O bank is unassigned.

To automatically assign technologies to I/O banks, choose **I/O Bank Assigner** from the **Tools** menu (or click the I/O Bank Assigner's toolbar button, shown in Figure 8-17).

Figure 8-17 • I/O Bank Assigner's Toolbar Button

Messages will appear in the Output window informing you when the automatic I/O bank assignment begins and ends. If the assignment is successful, the message "I/O Bank Assigner completed successfully" appears in the Output window, as shown in Figure 8-18.

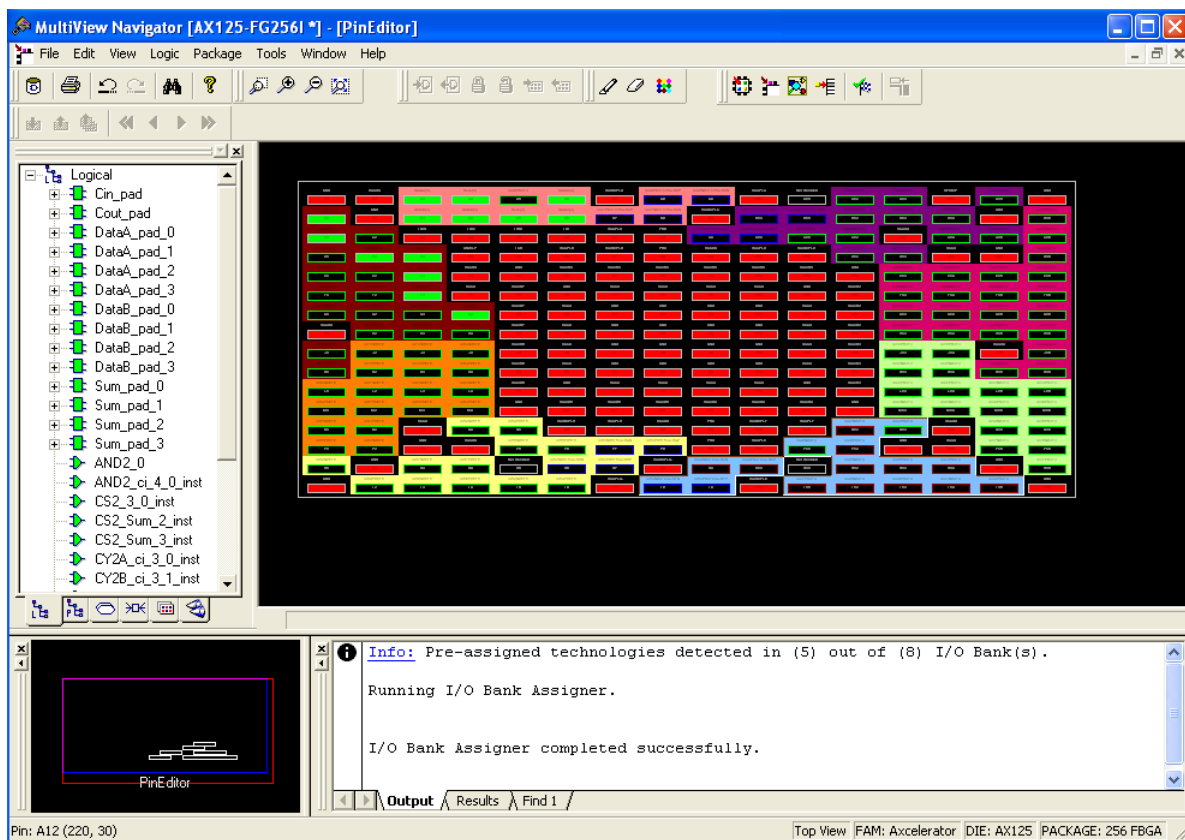

Figure 8-18 • I/O Bank Assigner Displays Messages in Output Window

If the assignment is not successful, an error message appears in the Output window.

To undo the I/O bank assignments, choose **Undo** from the **Edit** menu. Undo removes the I/O technologies assigned by the IOBA. It does not remove the I/O technologies previously assigned.

To redo the changes undone by the Undo command, choose **Redo** from the **Edit** menu.

To clear I/O bank assignments made before using the Undo command, manually unassign or reassign I/O technologies to banks. To do so, choose **I/O Bank Settings** from the **Edit** menu to display the I/O Bank Settings dialog box.

Conclusion

Actel Fusion, IGLOO, and ProASIC3 support for multiple I/O standards minimizes board-level components and makes possible a wide variety of applications. The Actel Designer software, integrated with Actel Libero IDE, presents a clear visual display of I/O assignments, allowing users to verify I/O and board-level design requirements before programming the device. The device I/O features and functionalities ensure board designers can produce low-cost and low-power FPGA applications fulfilling the complexities of contemporary design needs.

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the document.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 8-1 · Flash-Based FPGAs .	8-2
	The notes for Table 8-2 · Designer State (resulting from I/O attribute modification) were revised to indicate that skew control and input delay do not apply to nano devices.	8-3
v1.2 (June 2008)	The " Flash FPGAs I/O Support " section was revised to include new families and make the information more concise.	8-2
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 8-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> • ProASIC3L was updated to include 1.5 V. • The number of PLLs for ProASIC3E was changed from five to six. 	8-2
v1.0 (January 2008)	This document was previously part of the <i>I/O Structures in IGLOO and ProASIC3 Devices</i> document. The content was separated and made into a new document.	N/A
	Table 8-2 · Designer State (resulting from I/O attribute modification) was updated to include note 2 for IGLOO PLUS.	8-3

9 – DDR for Actel’s Low-Power Flash Devices

Introduction

The I/Os in Fusion, IGLOO,® and ProASIC®3 devices support Double Data Rate (DDR) mode. In this mode, new data is present on every transition (or clock edge) of the clock signal. This mode doubles the data transfer rate compared with Single Data Rate (SDR) mode, where new data is present on one transition (or clock edge) of the clock signal. Low-power flash devices have DDR circuitry built into the I/O tiles. I/Os are configured to be DDR receivers or transmitters by instantiating the appropriate special macros (examples shown in [Figure 9-4 on page 9-6](#) and [Figure 9-5 on page 9-7](#)) and buffers (DDR_OUT or DDR_REG) in the RTL design. This document discusses the options the user can choose to configure the I/Os in this mode and how to instantiate them in the design.

Double Data Rate (DDR) Architecture

Low-power flash devices support 350 MHz DDR inputs and outputs. In DDR mode, new data is present on every transition of the clock signal. Clock and data lines have identical bandwidths and signal integrity requirements, making them very efficient for implementing very high-speed systems. High-speed DDR interfaces can be implemented using LVDS. In IGLOOe, ProASIC3E, AFS600, and AFS1500 devices, DDR interfaces can also be implemented using the HSTL, SSTL, and LVPECL I/O standards. The DDR feature is primarily implemented in the FPGA core periphery and is not tied to a specific I/O technology or limited to any I/O standard.

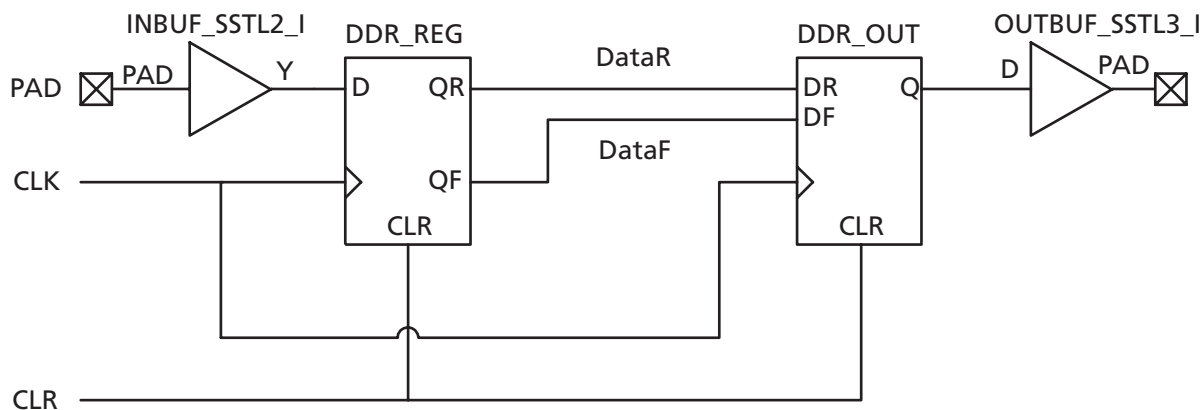

Figure 9-1 • DDR Support in Low-Power Flash Devices

DDR Support in Flash-Based Devices

The flash FPGAs listed in [Table 9-1](#) support the DDR feature and the functions described in this document.

Table 9-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 9-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 9-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

I/O Cell Architecture

Low-power flash devices support DDR in the I/O cells in four different modes: Input, Output, Tristate, and Bidirectional pins. For each mode, different I/O standards are supported, with most I/O standards having special sub-options. For the ProASIC3 nano and IGLOO nano devices, DDR is supported only in the 60 k, 125 k, and 250 k logic densities. Refer to [Table 9-2](#) for a sample of the available I/O options. Additional I/O options can be found in the relevant family datasheet.

Table 9-2 • DDR I/O Options

DDR Register Type	I/O Type	I/O Standard	Sub-Options	Comments
Receive Register	Input	Normal	None	3.3 V TTL (default)
		LVCMOS	Voltage	1.5 V, 1.8 V, 2.5 V, 5 V (1.5 V default)
			Pull-Up	None (default)
		PCI/PCI-X	None	
		GTL/GTL+	Voltage	2.5 V, 3.3 V (3.3 V default)
		HSTL	Class	I / II (I default)
		SSTL2/SSTL3	Class	I / II (I default)
		LVPECL	None	
LVDS	None			
Transmit Register	Output	Normal	None	3.3 V TTL (default)
		LVTTTL	Output Drive	2, 4, 6, 8, 12, 16, 24, 36 mA (8 mA default)
			Slew Rate	Low/high (high default)
		LVCMOS	Voltage	1.5 V, 1.8 V, 2.5 V, 5 V (1.5 V default)
		PCI/PCI-X	None	
		GTL/GTL+	Voltage	1.8 V, 2.5 V, 3.3 V (3.3 V default)
		HSTL	Class	I / II (I default)
		SSTL2/SSTL3	Class	I / II (I default)
		LVPECL	None	
LVDS	None			

Table 9-2 • DDR I/O Options (continued)

DDR Register Type	I/O Type	I/O Standard	Sub-Options	Comments
Transmit Register (continued)	Tristate Buffer	Normal	Enable Polarity	Low/high (low default)
		LVTTTL	Output Drive	2, 4, 6, 8, 12, 16, 24, 36 mA (8 mA default)
			Slew Rate	Low/high (high default)
			Enable Polarity	Low/high (low default)
			Pull-Up/-Down	None (default)
		LVCMOS	Voltage	1.5 V, 1.8 V, 2.5 V, 5 V (1.5 V default)
			Output Drive	2, 4, 6, 8, 12, 16, 24, 36 mA (8 mA default)
			Slew Rate	Low/high (high default)
			Enable Polarity	Low/high (low default)
		PCI/PCI-X	Enable Polarity	Low/high (low default)
		GTL/GTL+	Voltage	1.8 V, 2.5 V, 3.3 V (3.3 V default)
			Enable Polarity	Low/high (low default)
		HSTL	Class	I / II (I default)
			Enable Polarity	Low/high (low default)
		SSTL2/SSTL3	Class	I / II (I default)
			Enable Polarity	Low/high (low default)
		Bidirectional Buffer	Normal	Enable Polarity
	LVTTTL		Output Drive	2, 4, 6, 8, 12, 16, 24, 36 mA (8 mA default)
			Slew Rate	Low/high (high default)
			Enable Polarity	Low/high (low default)
			Pull-Up/-Down	None (default)
	LVCMOS		Voltage	1.5 V, 1.8 V, 2.5 V, 5 V (1.5 V default)
			Enable Polarity	Low/high (low default)
			Pull-Up	None (default)
	PCI/PCI-X		None	
			Enable Polarity	Low/high (low default)
	GTL/GTL+		Voltage	1.8 V, 2.5 V, 3.3 V (3.3 V default)
			Enable Polarity	Low/high (low default)
	HSTL		Class	I / II (I default)
Enable Polarity			Low/high (low default)	
SSTL2/SSTL3	Class		I / II (I default)	
	Enable Polarity		Low/high (low default)	

Input Support for DDR

The basic structure to support a DDR input is shown in Figure 9-2. Three input registers are used to capture incoming data, which is presented to the core on each rising edge of the I/O register clock. Each I/O tile supports DDR inputs.

Figure 9-2 • DDR Input Register Support in Low-Power Flash Devices

Output Support for DDR

The basic DDR output structure is shown in Figure 9-1 on page 9-1. New data is presented to the output every half clock cycle.

Note: DDR macros and I/O registers do not require additional routing. The combiner automatically recognizes the DDR macro and pushes its registers to the I/O register area at the edge of the chip. The routing delay from the I/O registers to the I/O buffers is already taken into account in the DDR macro.

Figure 9-3 • DDR Output Register (SSTL3 Class I)

Instantiating DDR Registers

Using SmartGen is the simplest way to generate the appropriate RTL files for use in the design. Figure 9-4 shows an example of using SmartGen to generate a DDR SSTL2 Class I input register. SmartGen provides the capability to generate all of the DDR I/O cells as described. The user, through the graphical user interface, can select from among the many supported I/O standards. The output formats supported are Verilog, VHDL, and EDIF.

Figure 9-5 on page 9-7 through Figure 9-8 on page 9-10 show the I/O cell configured for DDR using SSTL2 Class I technology. For each I/O standard, the I/O pad is buffered by a special primitive that indicates the I/O standard type.

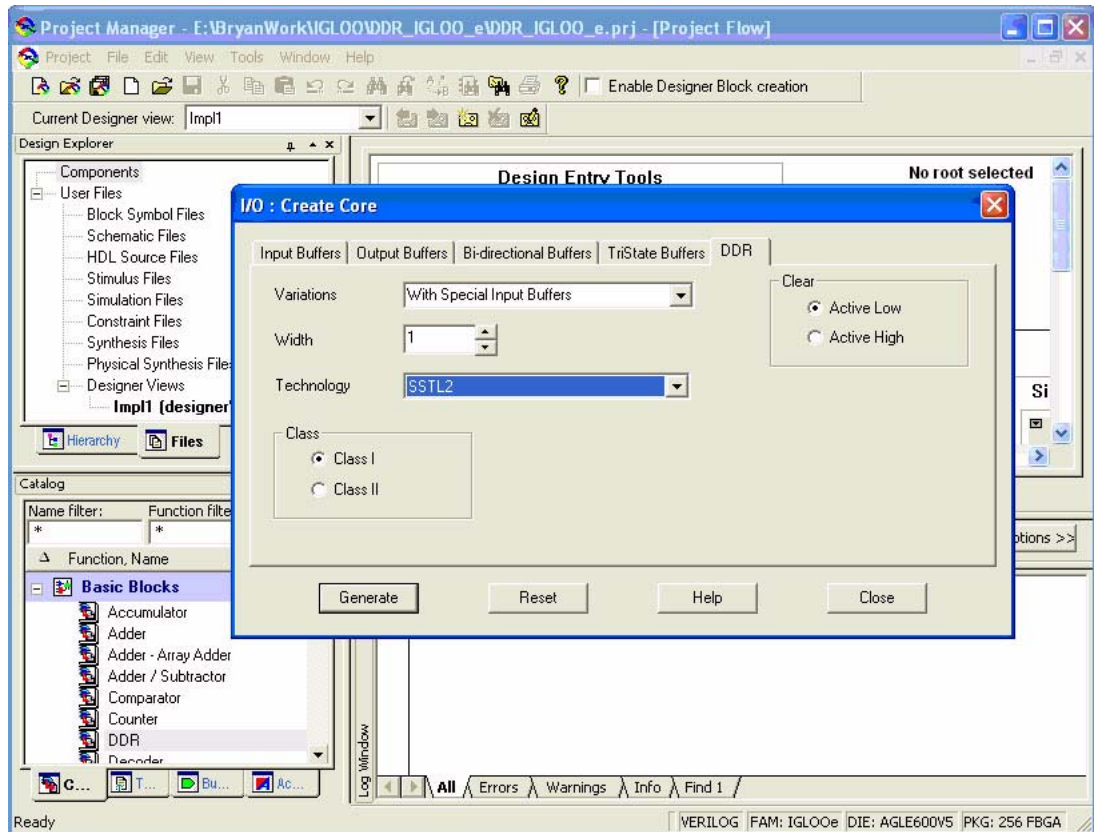

Figure 9-4 • Example of Using SmartGen to Generate a DDR SSTL2 Class I Input Register

DDR Input Register

Figure 9-5 • DDR Input Register (SSTL2 Class I)

The corresponding structural representations, as generated by SmartGen, are shown below:

Verilog

```
module DDR_InBuf_SSTL2_I(PAD,CLR,CLK,QR,QF);

input  PAD, CLR, CLK;
output QR, QF;

wire Y;

    INBUF_SSTL2_I INBUF_SSTL2_I_0_inst(.PAD(PAD),.Y(Y));
    DDR_REG DDR_REG_0_inst(.D(Y),.CLK(CLK),.CLR(CLR),.QR(QR),.QF(QF));

endmodule
```

VHDL

```

Design Example

Figure 9-9 shows a simple example of a design using both DDR input and DDR output registers. The user can copy the HDL code in Actel Libero® Integrated Design Environment (IDE) and go through the design flow. Figure 9-10 and Figure 9-11 on page 9-13 show the netlist and ChipPlanner views of the ddr_test design. Diagrams may vary slightly for different families.

Figure 9-9 • Design Example

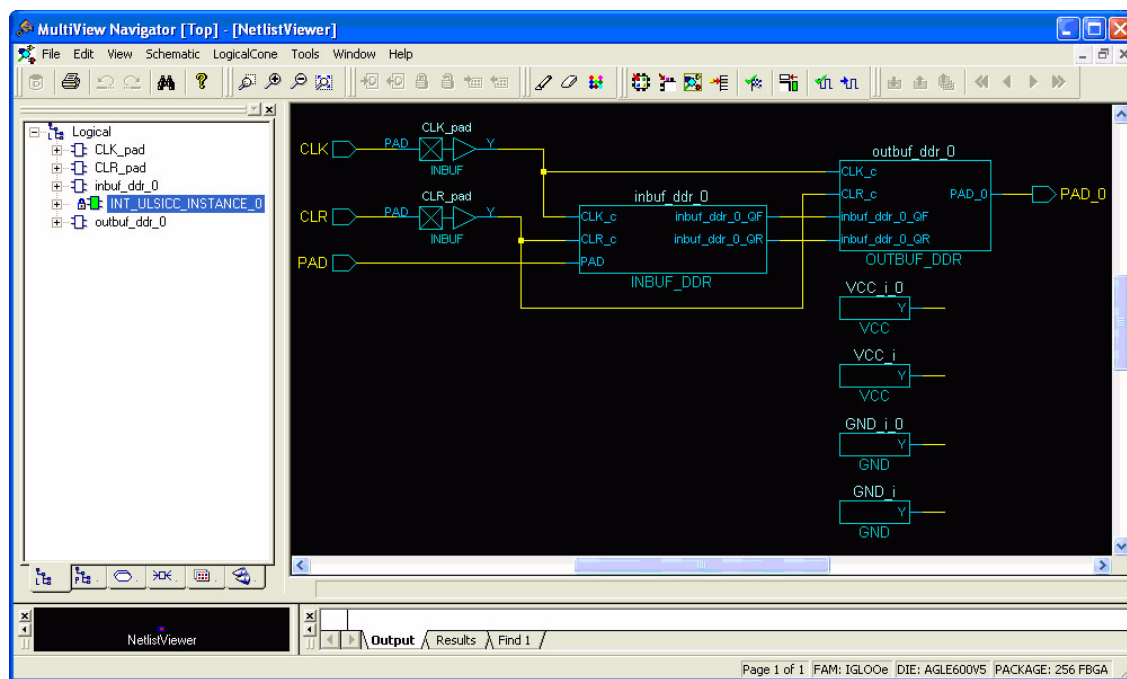

Figure 9-10 • DDR Test Design as Seen by NetlistViewer for IGLOO/e Devices

Figure 9-11 • DDR Input/Output Cells as Seen by ChipPlanner for IGLOO/e Devices

Verilog

```

module Inbuf_ddr(PAD,CLR,CLK,QR,QF);

input PAD, CLR, CLK;
output QR, QF;

wire Y;

    DDR_REG DDR_REG_0_inst(.D(Y), .CLK(CLK), .CLR(CLR), .QR(QR), .QF(QF));
    INBUF INBUF_0_inst(.PAD(PAD), .Y(Y));

endmodule

module Outbuf_ddr(DataR,DataF,CLR,CLK,PAD);

input DataR, DataF, CLR, CLK;
output PAD;

wire Q, VCC;

    VCC VCC_1_net(.Y(VCC));
    DDR_OUT DDR_OUT_0_inst(.DR(DataR), .DF(DataF), .CLK(CLK), .CLR(CLR), .Q(Q));
    OUTBUF OUTBUF_0_inst(.D(Q), .PAD(PAD));

endmodule

```

```
module ddr_test(DIN, CLK, CLR, DOUT);  
  
input  DIN, CLK, CLR;  
output DOUT;  
  
    Inbuf_dds Inbuf_dds (.PAD(DIN), .CLR(clr), .CLK(clk), .QR(qr), .QF(qf));  
    Outbuf_dds Outbuf_dds (.DataR(qr), .DataF(qf), .CLR(clr), .CLK(clk), .PAD(DOUT));  
  
    INBUF INBUF_CLR (.PAD(CLR), .Y(clr));  
    INBUF INBUF_CLK (.PAD(CLK), .Y(clk));  
  
endmodule
```

Simulation Consideration

Actel DDR simulation models use inertial delay modeling by default (versus transport delay modeling). As such, pulses that are shorter than the actual gate delays should be avoided, as they will not be seen by the simulator and may be an issue in post-routed simulations. The user must be aware of the default delay modeling and must set the correct delay model in the simulator as needed.

Conclusion

Fusion, IGLOO, and ProASIC3 devices support a wide range of DDR applications with different I/O standards and include built-in DDR macros. The powerful capabilities provided by SmartGen and its GUI can simplify the process of including DDR macros in designs and minimize design errors. Additional considerations should be taken into account by the designer in design floorplanning and placement of I/O flip-flops to minimize datapath skew and to help improve system timing margins. Other system-related issues to consider include PLL and clock partitioning.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in the Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 9-1 · Flash-Based FPGAs .	9-2
	The " I/O Cell Architecture " section was updated with information applicable to nano devices.	9-3
	The output buffer (OUTBUF_SSTL3_I) input was changed to D, instead of Q, in Figure 9-1 · DDR Support in Low-Power Flash Devices , Figure 9-3 · DDR Output Register (SSTL3 Class I) , Figure 9-6 · DDR Output Register (SSTL3 Class I) , Figure 9-7 · DDR Tristate Output Register, LOW Enable, 8 mA, Pull-Up (LVTTL) , and the output from the DDR_OUT macro was connected to the input of the TRIBUFF macro in Figure 9-7 · DDR Tristate Output Register, LOW Enable, 8 mA, Pull-Up (LVTTL) .	9-1, 9-5, 9-8, 9-9
v1.2 (June 2008)	The " Double Data Rate (DDR) Architecture " section was updated to include mention of the AFS600 and AFS1500 devices.	9-1
	The " DDR Support in Flash-Based Devices " section was revised to include new families and make the information more concise.	9-2
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 9-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> • ProASIC3L was updated to include 1.5 V. • The number of PLLs for ProASIC3E was changed from five to six. 	9-2
v1.0 (January 2008)	The " IGLOO Terminology " section and " ProASIC3 Terminology " section are new.	9-2

Packaging and Pin Descriptions

10 – Pin Descriptions

Supply Pins

GND **Ground**

Ground supply voltage to the core, I/O outputs, and I/O logic.

GNDQ **Ground (quiet)**

Quiet ground supply voltage to input buffers of I/O banks. Within the package, the GNDQ plane is decoupled from the simultaneous switching noise originated from the output buffer ground domain. This minimizes the noise transfer within the package and improves input signal integrity. GNDQ must always be connected to GND on the board.

V_{CC} **Core Supply Voltage**

Supply voltage to the FPGA core, nominally 1.5 V for ProASIC[®]3/E devices, 1.5 V for IGLOO[®]/e V5 devices, and 1.2 V or 1.5 V for IGLOO/e V2 and ProASIC3L devices. V_{CC} is required for powering the JTAG state machine in addition to V_{JTAG}. Even when a device is in bypass mode in a JTAG chain of interconnected devices, both V_{CC} and V_{JTAG} must remain powered to allow JTAG signals to pass through the device.

For IGLOO/e V2 and ProASIC3L devices, V_{CC} can be switched dynamically from 1.2 V to 1.5 V or vice versa. This allows in-system programming (ISP) when V_{CC} is at 1.5 V and the benefit of low-power operation when V_{CC} is at 1.2 V.

V_{CCi}B_x **I/O Supply Voltage**

Supply voltage to the bank's I/O output buffers and I/O logic. B_x is the I/O bank number. There are up to eight I/O banks on low-power flash devices plus a dedicated V_{JTAG} bank. Each bank can have a separate V_{CCi} connection. All I/Os in a bank will run off the same V_{CCi}B_x supply. V_{CCi} can be 1.2 V (not supported on ProASIC3/E devices), 1.5 V, 1.8 V, 2.5 V, or 3.3 V, nominal voltage. Unused I/O banks should have their corresponding V_{CCi} pins tied to GND.

VMV_x **I/O Supply Voltage (quiet)**

Quiet supply voltage to the input buffers of each I/O bank. x is the bank number. Within the package, the VMV plane is decoupled from the simultaneous switching noise originating from the output buffer V_{CCi} domain. This minimizes the noise transfer within the package and improves input signal integrity. Each bank must have at least one VMV connection, and no VMV should be left unconnected. All I/Os in a bank run off the same VMV_x supply. VMV is used to provide a quiet supply voltage to the input buffers of each I/O bank. VMV_x can be 1.2 V (ProASIC3L and IGLOO/e devices only), 1.5 V, 1.8 V, 2.5 V, or 3.3 V, nominal voltage. Unused I/O banks should have their corresponding VMV pins tied to GND. VMV and V_{CCi} should be at the same voltage within a given I/O bank. Used VMV pins must be connected to the corresponding V_{CCi} pins of the same bank (i.e., VMV0 to V_{CCi}B0, VMV1 to V_{CCi}B1, etc.).

V_{CCPLA/B/C/D/E/F} **PLL Supply Voltage**

Supply voltage to analog PLL, nominally 1.5 V or 1.2 V, depending on the device family.

- 1.5 V for IGLOO V5, IGLOOe V5, ProASIC3, and ProASIC3E devices
- 1.2 V or 1.5 V for IGLOO V2, IGLOOe V2, ProASIC3L, and ProASIC3EL devices

When the PLLs are not used, the Actel Designer place-and-route tool automatically disables the unused PLLs to lower power consumption. The user should tie unused V_{CCPLX} and V_{COMPLX} pins to ground. Actel recommends tying V_{CCPLX} to V_{CC} and using proper filtering circuits to decouple V_{CC} noise from the PLLs. Refer to the PLL Power Supply Decoupling section of [Clock Conditioning Circuits in IGLOO and ProASIC3 Devices](#) for a complete board solution for the PLL analog power supply and ground.

- There is one V_{CCPLF} pin on IGLOO, IGLOO PLUS, ProASIC3L, and ProASIC3 devices.
- There are six V_{CCPLX} pins on IGLOOe, ProASIC3EL, and ProASIC3E devices.

V_{COMPLA/B/C/D/E/F} PLL Ground

Ground to analog PLL power supplies. When the PLLs are not used, the Actel Designer place-and-route tool automatically disables the unused PLLs to lower power consumption. The user should tie unused V_{CCPLX} and V_{COMPLX} pins to ground.

- There is one V_{COMPLF} pin on IGLOO, ProASIC3L, and ProASIC3 devices.
- There are six V_{COMPL} pins (PLL ground) on IGLOOe, ProASIC3EL, and ProASIC3E devices.

V_{JTAG} JTAG Supply Voltage

Low-power flash devices have a separate bank for the dedicated JTAG pins. The JTAG pins can be run at any voltage from 1.5 V to 3.3 V (nominal). Isolating the JTAG power supply in a separate I/O bank gives greater flexibility in supply selection and simplifies power supply and PCB design. If the JTAG interface is neither used nor planned for use, the V_{JTAG} pin together with the TRST pin could be tied to GND. It should be noted that V_{CC} is required to be powered for JTAG operation; V_{JTAG} alone is insufficient. If a device is in a JTAG chain of interconnected boards, the board containing the device can be powered down, provided both V_{JTAG} and V_{CC} to the part remain powered; otherwise, JTAG signals will not be able to transition the device, even in bypass mode.

Actel recommends that V_{PUMP} and V_{JTAG} power supplies be kept separate with independent filtering capacitors rather than supplying them from a common rail.

V_{PUMP} Programming Supply Voltage

IGLOO, ProASIC3L, and ProASIC3 devices support single-voltage ISP of the configuration flash and FlashROM. For programming, V_{PUMP} should be 3.3 V nominal. During normal device operation, V_{PUMP} can be left floating or can be tied (pulled up) to any voltage between 0 V and the V_{PUMP} maximum. Programming power supply voltage (V_{PUMP}) range is listed in the datasheet.

When the V_{PUMP} pin is tied to ground, it will shut off the charge pump circuitry, resulting in no sources of oscillation from the charge pump circuitry.

For proper programming, 0.01 μ F and 0.33 μ F capacitors (both rated at 16 V) are to be connected in parallel across V_{PUMP} and GND, and positioned as close to the FPGA pins as possible.

Actel recommends that V_{PUMP} and V_{JTAG} power supplies be kept separate with independent filtering capacitors rather than supplying them from a common rail.

User-Defined Supply Pins

V_{REF} I/O Voltage Reference

Reference voltage for I/O minibanks in IGLOOe, ProASIC3EL, and ProASIC3E devices. V_{REF} pins are configured by the user from regular I/Os, and any I/O in a bank, except JTAG I/Os, can be designated the voltage reference I/O. Only certain I/O standards require a voltage reference—HSTL (I) and (II), SSTL2 (I) and (II), SSTL3 (I) and (II), and GTL/GTL+. One V_{REF} pin can support the number of I/Os available in its minibank.

User Pins

I/O User Input/Output

The I/O pin functions as an input, output, tristate, or bidirectional buffer. Input and output signal levels are compatible with the I/O standard selected.

During programming, I/Os become tristated and weakly pulled up to V_{CCI} . With V_{CCI} , V_{MV} , and V_{CC} supplies continuously powered up, when the device transitions from programming to operating mode, the I/Os are instantly configured to the desired user configuration.

Unused I/Os are configured as follows:

- Output buffer is disabled (with tristate value of high impedance)
- Input buffer is disabled (with tristate value of high impedance)
- Weak pull-up is programmed

GL Globals

GL I/Os have access to certain clock conditioning circuitry (and the PLL) and/or have direct access to the global network (spines). Additionally, the global I/Os can be used as regular I/Os, since they have identical capabilities. Unused GL pins are configured as inputs with pull-up resistors.

See more detailed descriptions of global I/O connectivity in [Clock Conditioning Circuits in IGLOO and ProASIC3 Devices](#). All inputs labeled GC/GF are direct inputs into the quadrant clocks. For example, if GAA0 is used for an input, GAA1 and GAA2 are no longer available for input to the quadrant globals. All inputs labeled GC/GF are direct inputs into the chip-level globals, and the rest are connected to the quadrant globals. The inputs to the global network are multiplexed, and only one input can be used as a global input.

Refer to the I/O Structure section of the handbook for the device you are using for an explanation of the naming of global pins.

FF Flash*Freeze Mode Activation Pin

Flash*Freeze is available on IGLOO, ProASIC3L, and RT ProASIC3 devices. It is not supported on ProASIC3/E devices. The FF pin is a dedicated input pin used to enter and exit Flash*Freeze mode. The FF pin is active-low, has the same characteristics as a single-ended I/O, and must meet the maximum rise and fall times. When Flash*Freeze mode is not used in the design, the FF pin is available as a regular I/O. For IGLOOe, ProASIC3EL, and RT ProASIC3 only, the FF pin can be configured as a Schmitt trigger input.

When Flash*Freeze mode is used, the FF pin must not be left floating to avoid accidentally entering Flash*Freeze mode. While in Flash*Freeze mode, the Flash*Freeze pin should be constantly asserted.

The Flash*Freeze pin can be used with any single-ended I/O standard supported by the I/O bank in which the pin is located, and input signal levels compatible with the I/O standard selected. The FF pin should be treated as a sensitive asynchronous signal. When defining pin placement and board layout, simultaneously switching outputs (SSOs) and their effects on sensitive asynchronous pins must be considered.

Unused FF or I/O pins are tristated with weak pull-up. This default configuration applies to both Flash*Freeze mode and normal operation mode. No user intervention is required.

Table 10-1 shows the Flash*Freeze pin location on the available packages for IGLOO and ProASIC3L devices. The Flash*Freeze pin location is independent of device (except for a PQ208 package), allowing migration to larger or smaller IGLOO devices while maintaining the same pin location on the board. Refer to *Flash*Freeze Technology and Low-Power Modes in IGLOO and ProASIC3L Devices* for more information on I/O states during Flash*Freeze mode.

Table 10-1 • Flash*Freeze Pin Location in IGLOO and ProASIC3L Family Packages (device-independent)

IGLOO and ProASIC3L Packages	Flash*Freeze Pin
CS81/UC81	H2
CS121	J5
CS196	P3
QN48	14
QN68	18
QN132	B12

PQ2097-A3P1000L	55
PQ208-A3PE3000L	58

JTAG Pins

Low-power flash devices have a separate bank for the dedicated JTAG pins. The JTAG pins can be run at any voltage from 1.5 V to 3.3 V (nominal). V_{CC} must also be powered for the JTAG state machine to operate, even if the device is in bypass mode; V_{JTAG} alone is insufficient. Both V_{JTAG} and V_{CC} to the part must be supplied to allow JTAG signals to transition the device. Isolating the JTAG power supply in a separate I/O bank gives greater flexibility in supply selection and simplifies power supply and PCB design. If the JTAG interface is neither used nor planned for use, the V_{JTAG} pin together with the TRST pin could be tied to GND.

TCK Test Clock

Test clock input for JTAG boundary scan, ISP, and UJTAG. The TCK pin does not have an internal pull-up/down resistor. If JTAG is not used, Actel recommends tying off TCK to GND through a resistor placed close to the FPGA pin. This prevents JTAG operation in case TMS enters an undesired state.

Note that to operate at all V_{JTAG} voltages, 500 Ω to 1 k Ω will satisfy the requirements. Refer to Table 10-2 for more information.

Table 10-2 • Recommended Tie-Off Values for the TCK and TRST Pins

V_{JTAG}	Tie-Off Resistance
V_{JTAG} at 3.3 V	200 Ω to 1 k Ω
V_{JTAG} at 2.5 V	200 Ω to 1 k Ω
V_{JTAG} at 1.8 V	500 Ω to 1 k Ω
V_{JTAG} at 1.5 V	500 Ω to 1 k Ω

Notes:

1. Equivalent parallel resistance if more than one device is on the JTAG chain
2. The TCK pin can be pulled up/down.
3. The TRST pin is pulled down.

TDI Test Data Input

Serial input for JTAG boundary scan, ISP, and UJTAG usage. There is an internal weak pull-up resistor on the TDI pin.

TDO Test Data Output

Serial output for JTAG boundary scan, ISP, and UJTAG usage.

TMS Test Mode Select

The TMS pin controls the use of the IEEE 1532 boundary scan pins (TCK, TDI, TDO, TRST). There is an internal weak pull-up resistor on the TMS pin.

TRST Boundary Scan Reset Pin

The TRST pin functions as an active-low input to asynchronously initialize (or reset) the boundary scan circuitry. There is an internal weak pull-up resistor on the TRST pin. If JTAG is not used, an external pull-down resistor could be included to ensure the test access port (TAP) is held in reset mode. The resistor values must be chosen from Table 10-2 and must satisfy the parallel resistance value requirement. The values in Table 10-2 correspond to the resistor recommended when a single device is used, and the equivalent parallel resistor when multiple devices are connected via a JTAG chain.

In critical applications, an upset in the JTAG circuit could allow entrance to an undesired JTAG state. In such cases, Actel recommends tying off TRST to GND through a resistor placed close to the FPGA pin.

Note that to operate at all V_{JTAG} voltages, 500 Ω to 1 k Ω will satisfy the requirements.

Special Function Pins

NC**No Connect**

This pin is not connected to circuitry within the device. These pins can be driven to any voltage or can be left floating with no effect on the operation of the device.

DC**Do Not Connect**

This pin should not be connected to any signals on the PCB. These pins should be left unconnected.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet. To improve usability for customers, the device architecture information has now been split into handbook sections, which also include usage information. No technical changes were made to the content unless explicitly listed.

Part Number 51700094-011-3

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.3)	Page
v1.2 (October 2008)	<p>Table 10-1 · Flash*Freeze Pin Location in IGLOO and ProASIC3L Family Packages (device-independent) was updated as follows:</p> <p>The QN48, VQ128, and VQ176 packages were added.</p> <p>The note that CS201 and CS289 packages are available only for IGLOO PLUS devices was removed.</p> <p>U1 was designated as the Flash*Freeze pin for the CS289 package.</p>	10-4
v1.1 (March 2008)	The "FF Flash*Freeze Mode Activation Pin" section was updated to include RT ProASIC3 devices.	10-3
	CG/LG484 and CG/LG896 were added to Table 10-1 · Flash*Freeze Pin Location in IGLOO and ProASIC3L Family Packages (device-independent).	10-4
v1.0 (January 2008)	The "VCCIBx I/O Supply Voltage" section was revised to note that 1.2 V is not supported for ProASIC3/E devices. The "VMVx I/O Supply Voltage (quiet)" section was updated to state that VMVx can also be 1.2 V nominal voltage on ProASIC3L and IGLOO/e devices.	10-1
	The "Handbook Documents" section was revised to include the three different I/O Structures chapters for IGLOO and ProASIC3 device families.	10-6
	The " $V_{CCPLA/B/C/D/E/F}$ PLL Supply Voltage" section and " $V_{COMPLA/B/C/D/E/F}$ PLL Ground" section were revised. The " V_{CCPLF} PLL Supply Voltage" section and " V_{COMPLF} PLL Ground" section were removed.	10-1 to 10-2
	The following packages were added to Table 10-1 · Flash*Freeze Pin Location in IGLOO and ProASIC3L Family Packages (device-independent): UC81, QN68, CS201, and CS289. Flash*Freeze pin W2 was specified for the CS281 package. The PG208 package was changed to the correct designation of PQ208.	10-4

11 – Packaging

Semiconductor technology is constantly shrinking in size while growing in capability and functional integration. To enable next-generation silicon technologies, semiconductor packages have also evolved to provide improved performance and flexibility.

Actel consistently delivers packages that provide the necessary mechanical and environmental protection to ensure consistent reliability and performance. Actel IC packaging technology efficiently supports high-density FPGAs with large-pin-count Ball Grid Arrays (BGAs), but is also flexible enough to accommodate stringent form factor requirements for Chip Scale Packaging (CSP). In addition, Actel offers a variety of packages designed to meet your most demanding application and economic requirements for today's embedded and mobile systems.

The following documents provide packaging information and device selection for low-power flash devices.

Product Catalog

http://www.actel.com/documents/ProdCat_PIB.pdf

Lists devices currently recommended for new designs and the packages available for each member of the family. Use this document or the datasheet tables to determine the best package for your design, and which package drawing to use.

Package Mechanical Drawings

<http://www.actel.com/documents/PckgMechDrwns.pdf>

This document contains the package mechanical drawings for all packages currently or previously supplied by Actel. Use the bookmarks to navigate to the package mechanical drawings.

Related Documents

Additional packaging materials are available at <http://www.actel.com/products/solutions/package/docs.aspx>.

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

v1.0 (January 2008)	This document now references the Product Catalog, which replaced the Product Selector Guide.	1

Programming and Security

12 – Programming Flash Devices

Introduction

This document provides an overview of the various programming options available for the Actel flash families. The electronic version of this document includes active links to all programming resources, which are available at <http://www.actel.com/products/hardware/default.aspx>. For Actel antifuse devices, refer to the *Programming Antifuse Devices* document.

Summary of Programming Support

FlashPro3 is a high-performance in-system programming (ISP) tool targeted at the latest generation of low-power flash devices offered by Actel: Fusion, IGLOO®, and ProASIC®3, including ARM®-enabled devices. FlashPro3 offers extremely high performance through the use of USB 2.0, is high-speed compliant for full use of the 480 Mbps bandwidth, and can program ProASIC3 devices in under 30 seconds. Powered exclusively via USB, FlashPro3 provides a V_{PUMP} voltage of 3.3 V for programming these devices.

Silicon Sculptor 3 is an easy-to-use, single-site programming tool for Actel FPGAs that delivers high data throughput and promotes ease of use while lowering the overall cost of ownership. Silicon Sculptor 3 includes a high-speed USB 2.0 interface that allows a customer to connect as many as 12 programmers to a single PC. Furthermore, Silicon Sculptor 3 is compatible with adapter modules from Silicon Sculptor II, thereby preserving a customer's investment and enabling a seamless upgrade to this latest generation of the tool.

For details of programmer support for each device, refer to [Table 12-6 on page 12-10](#).

Figure 12-1 • FlashPro Programming Setup

Programming Support in Flash Devices

The flash FPGAs listed in [Table 12-1](#) support flash in-system programming and the functions described in this document.

Table 12-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device
ProASIC	ProASIC	First generation ProASIC devices
	ProASIC^{PLUS}	Second generation ProASIC devices

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 12-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 12-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

General Flash Programming Information

Programming Basics

When choosing a programming solution, there are a number of options available. This section provides a brief overview of those options. The next sections provide more detail on those options as they apply to Actel FPGAs.

Reprogrammable or One-Time-Programmable (OTP)

Depending on the technology chosen, devices may be reprogrammable or one-time-programmable. As the name implies, a reprogrammable device can be programmed many times. Generally, the contents of such a device will be completely overwritten when it is reprogrammed. All Actel flash devices are reprogrammable.

An OTP device is programmable one time only. Once programmed, no more changes can be made to the contents. Actel flash devices provide the option of disabling the reprogrammability for security purposes. This combines the convenience of reprogrammability during design verification with the security of an OTP technology for highly sensitive designs.

Device Programmer or In-System Programming

There are two fundamental ways to program an FPGA: using a device programmer or, if the technology permits, using in-system programming. A device programmer is a piece of equipment in a lab or on the production floor that is used for programming devices. The devices are placed into a socket mounted in a programming adapter module, and the appropriate electrical interface is applied. The device can then be placed on the board. A typical programmer, used during development, programs a single device at a time and is referred to as a single-site engineering programmer.

With ISP, the device is already mounted onto the board when programming occurs, most typically via the JTAG pins. The JTAG pins can be controlled either by an on-board resource, such as a microprocessor, or by an off-board programmer through a header connection. Once mounted, it can be programmed repeatedly. If the application requires it, the system can be designed to reprogram itself using a microprocessor, without the use of any external programmer.

For production, high-volume multi-site production programmers handle designs that require device programmers. In addition, Actel can preprogram devices for production, negating the need for further programming. This service is referred to as in-house programming (IHP).

Live at Power-Up (LAPU) or Boot PROM

Utilizing the technology of the FPGA significantly impacts board-level power-up considerations. Some technologies are nonvolatile and are considered functional, or "live," as soon as power reaches the operational level. All Actel FPGA technologies are live at power-up. By contrast, SRAM technology is volatile, and devices built using SRAM cells lose their contents when power cycling occurs. These devices must be reprogrammed every time power is applied. Such a design must include nonvolatile storage for the contents as well as the means to reprogram. There is a delay before SRAM devices are functional; other parts of the board must come alive first to reprogram these types of FPGAs. Therefore, such devices can never be part of critical boot circuits.

Design Security

Design security is a growing concern for systems designers. The choice of programming methodology and technology affects system security. Use of Actel programming technology is the most secure option available, providing much better protection than SRAM-based devices and ASICs. Actel provides a number of ways to ensure designs are protected. General information on design security can be found on the Actel website:

<http://www.actel.com/products/solutions/security/default.aspx>

Programming Features for Actel Devices

Actel provides two types of FPGAs: flash and antifuse (Table 12-2). Some programming methods are common to both and some are exclusive to flash. This document describes only the programming solutions supported for flash devices.

Table 12-2 • Programming Features for Actel Devices

Feature	Flash	Antifuse
Reprogrammable	Yes	No
In-system programmable	Yes	No
One-time programmable	Yes (option)	Yes
Live at power-up	Yes	Yes
Secure	Yes	Yes
Single-site programmer support	Yes	Yes
Multi-site programmer support	Yes	Yes
In-house programming support	Yes	Yes

Flash Devices

The flash devices supplied by Actel are reprogrammable by either a generic device programmer or ISP. Actel supports ISP using JTAG, which is supported by the FlashPro3, FlashPro Lite, FlashPro, Silicon Sculptor 3, and Silicon Sculptor II programmers.

Levels of ISP support vary depending on the device chosen:

- All Fusion, IGLOO, and ProASIC3 devices support ISP.
- IGLOO, IGLOOe, IGLOO nano V5, and IGLOO PLUS devices can be programmed in-system when the device is using a 1.5 V supply voltage to the FPGA core.
- All IGLOO V2 and ProASIC3L devices can be operated at any voltage between 1.2 V and 1.5 V; the Designer software allows 50 mV increments in the voltage. Although the device can operate at 1.2 V core voltage, the device can only be reprogrammed when the core voltage is 1.5 V. Voltage switching is required in-system to switch from a 1.2 V supply (V_{CC} , V_{CC1} , and V_{JTAG}) to 1.5 V for programming.

Since flash devices are nonvolatile, they are live at power-up. This is different from an SRAM-based device, which loads its programming information when it is powered up. SRAM devices require a time on the order of hundreds of milliseconds before the system is active.

There are multiple levels of security available in flash devices. Use of a security key will lock the device. The device can then only be reprogrammed by first unlocking the device with the appropriate security key. It can also be locked permanently, which means there is no key that can access the device. The command to secure the device is embedded within the programming file, optionally enabled by the programming software. This is also referred to as the OTP version of flash, allowing for only a single programming instance. This is discussed in more detail in the [Implementation of Security in Actel's ProASIC and ProASIC^{PLUS} Flash-Based FPGAs](#) application note, and in the [Security in Low-Power Flash Devices](#) handbook section.

Flash devices can also be programmed using single-site or multi-site programmers as well as volume programming services from Actel or other vendors.

Types of Programming for Flash Devices

The number of devices to be programmed will influence the optimal programming methodology. Those available are listed below:

- In-system programming
 - Using a programmer
 - Using a microprocessor or microcontroller
- Device programmers
 - Single-site programmers
 - Multi-site programmers, batch programmers, or gang programmers
 - Automated production (robotic) programmers
- Volume programming services
 - Actel in-house programming
 - Programming centers

In-System Programming

Device Type Supported: Flash

ISP refers to programming the FPGA after it has been mounted on the system board. The FPGA may be preprogrammed and later reprogrammed using ISP.

The advantage of using ISP is the ability to update the FPGA design many times without any changes to the board. This eliminates the requirement of using a socket for the FPGA, saving cost and improving reliability. It also reduces programming hardware expenses, as the ISP methodology is die-/package-independent.

There are two methods of in-system programming: external and internal.

- Programmer ISP—Refer to *In-System Programming (ISP) of Actel's Low-Power Flash Devices Using FlashPro3* for more information.

Using an external programmer and a cable, the device can be programmed through a header on the system board. In Actel documentation, this is referred to as external ISP. Actel provides FlashPro3, FlashPro Lite, FlashPro, or Silicon Sculptor 3 to perform external ISP. Note that Silicon Sculptor II and Silicon Sculptor 3 can only provide ISP for ProASIC and ProASIC^{PLUS}® families, not for Fusion, IGLOO, or ProASIC3.

 - Advantages: Allows local control of programming and data files for maximum security. The programming algorithms and hardware are available from Actel. The only hardware required on the board is a programming header.
 - Limitations: A negligible board space requirement for the programming header and JTAG signal routing
- Microprocessor ISP—Refer to *Microprocessor Programming of Actel's Low-Power Flash Devices* for more information.

Using a microprocessor and an external or internal memory, you can store the program in memory and use the microprocessor to perform the programming. In Actel documentation, this is referred to as internal ISP. Both the code for the programming algorithm and the FPGA programming file must be stored in memory on the board. Programming voltages must also be generated on the board.

 - Advantages: The programming code is stored in the system memory. An external programmer is not required during programming.
 - Limitations: This is the approach that requires the most design work, since some way of getting and/or storing the data is needed; a system interface to the device must be designed; and the low-level API to the programming firmware must be written and linked into the code provided by Actel. While there are benefits to this methodology, serious thought and planning should go into the decision.

Device Programmers

Device Type Supported: Flash and Antifuse

Device programmers are used to program a device before it is mounted on the system board.

The advantage of using device programmers is that no programming hardware is required on the system board. Therefore, no additional components or board space are required.

If devices are to be reprogrammed multiple times, or if the quantity of devices to be programmed is relatively low, a single-site device programmer is the simplest solution. For applications in which design security is paramount (often the case in military or space designs), the use of on-site programming maintains design security at all times.

Adapter modules are purchased with the programmers to support the FPGA packages used. The FPGA is placed in the adapter module and the programming software is run from a PC. Actel supplies the programming software for all of the Actel programmers. The software allows for the selection of the correct die/package and programming files. It will then program and verify the device.

- Single-site programmers

A single-site programmer programs one device at a time. Actel offers Silicon Sculptor 3 as a single-site programmer.

- Advantages: Lower cost than multi-site programmers. No additional overhead for programming on the system board. Allows local control of programming and data files for maximum security. Allows on-demand programming on-site.
- Limitations: Only programs one device at a time.

- Multi-site programmers

Often referred to as batch or gang programmers, multi-site programmers can program multiple devices at the same time using the same programming file. This is often used for large volume programming and by programming houses. The sites often have independent processors and memory enabling the sites to operate concurrently, meaning each site may start programming the same file independently. This enables the operator to change one device while the other sites continue programming, which increases throughput. Multiple adapter modules for the same package are required when using a multi-site programmer. Silicon Sculptor I, II, and 3 programmers can be cascaded to program multiple devices in a chain. Multi-site programmers can also be purchased from BP Microsystems.

- Advantages: Provides the capability of programming multiple devices at the same time. No additional overhead for programming on the system board. Allows local control of programming and data files for maximum security.
- Limitations: More expensive than a single-site programmer

- Automated production (robotic) programmers

Automated production programmers are based on multi-site programmers. They consist of a large input tray holding multiple parts and a robotic arm to select and place parts into appropriate programming sockets automatically. When the programming of the parts is complete, the parts are removed and placed in a finished tray. The automated programmers are often used in volume programming houses to program parts for which the programming time is small.

Volume Programming Services

Device Type Supported: Flash and Antifuse

Once the design is stable for applications with large production volumes, preprogrammed devices can be purchased. Table 12-3 describes the volume programming services.

Table 12-3 • Volume Programming Services

Programmer	Vendor	Availability
In-House Programming	Actel	Contact Actel Sales
Distributor Programming Centers	Memec Unique	Contact Distribution
Independent Programming Centers	Various	Contact Vendor

Advantages: As programming is outsourced, this solution is easier to implement than creating a substantial in-house programming capability. As programming houses specialize in large-volume programming, this is often the most cost-effective solution.

Limitations: There are some logistical issues with the use of a programming service provider, such as the transfer of programming files and the approval of First Articles. By definition, the programming file must be released to a third-party programming house. Nondisclosure agreements (NDAs) can be signed to help ensure data protection; however, for extremely security-conscious designs, this may not be an option.

- Actel In-House Programming

When purchasing Actel devices in volume, IHP can be requested as part of the purchase. If this option is chosen, there is a small cost adder for each device programmed. Each device is marked with a special mark to distinguish it from blank parts. Programming files for the design will be sent to Actel. Sample parts with the design programmed, First Articles, will be returned for customer approval. Once approval of First Articles has been received, Actel will proceed with programming the remainder of the order. To request Actel IHP, contact your local Actel representative.

- Distributor Programming Centers

If purchases are made through a distributor, many distributors will provide programming for their customers. Consult with your preferred distributor about this option.

- Independent Programming Centers

There are many programming centers that specialize only in programming but are not directly affiliated with Actel or our distributors. These programming centers must follow the guidelines for programming Actel devices and use certified programmers to program Actel devices. Actel does not have recommendations for external programming centers.

Programming Solutions

Details for the available programmers can be found in the programmer user's guides listed in the "Related Documents" section on page 12-15. Refer to Table 12-6 on page 12-10 for more information concerning programming solutions.

All of the programmers except FlashPro3, FlashPro Lite, and FlashPro require adapter modules, which are designed to support device packages. The modules are all listed on the Actel website at http://www.actel.com/products/hardware/program_debug/ss/modules.aspx. They are not listed in this document, since this list is updated frequently with new package options and any upgrades required to improve programming yield or support new families.

Table 12-4 • Programming Solutions

Programmer	Vendor	ISP	Single Device	Multi-Device	Availability
FlashPro3	Actel	Only	Yes	Yes ¹	Available
FlashPro Lite	Actel	Only	Yes	Yes ¹	Available
FlashPro	Actel	Only	Yes	Yes ¹	Available
Silicon Sculptor 3	Actel	Yes ²	Yes	Cascade option (up to two)	Available
Silicon Sculptor II	Actel	Yes ²	Yes	Cascade option (up to two)	Available
Silicon Sculptor	Actel	Yes	Yes	Cascade option (up to four)	Discontinued
Sculptor 6X	Actel	No	Yes	Yes	Discontinued
BP MicroProgrammers	BP Microsystems	No	Yes	Yes	Contact BP Microsystems at www.bpmicro.com

Notes:

1. Multiple devices can be connected in the same JTAG chain for programming.
2. Silicon Sculptor II and Silicon Sculptor 3 can only provide ISP for ProASIC and ProASIC^{PLUS} families, not for Fusion, IGLoo, or ProASIC3 devices.

Programmer Ordering Codes

The products shown in Table 12-5 can be ordered through Actel sales and will be shipped directly from Actel. Products can also be ordered from Actel distributors, but will still be shipped directly from Actel. Table 12-5 includes ordering codes for the full kit, as well as codes for replacement items and any related hardware. Some additional products can be purchased from external suppliers for use with the programmers. Ordering codes for adapter modules used with Silicon Sculptor are available on the Actel website at

http://www.actel.com/products/hardware/program_debug/ss/modules.aspx.

Table 12-5 • Programming Ordering Codes

Description	Vendor	Ordering Code	Comment
FlashPro3 ISP programmer	Actel	FLASHPRO 3	Uses a 2x5, RA male header connector
FlashPro Lite ISP programmer	Actel	FLASHPRO LITE	Supports small programming header or large header through header converter (not included)
FlashPro ISP programmer	Actel	FLASH PRO	Supports small programming header or large header through header converter (not included)
Silicon Sculptor 3	Actel	SILICON-SCULPTOR 3	USB 2.0 high-speed production programmer
Silicon Sculptor II	Actel	SILICON-SCULPTOR II	Requires add-on adapter modules to support devices
Silicon Sculptor ISP module	Actel	SMPA-ISP-ACTEL-3-KIT	Ships with both large and small header support

* A maximum of two Silicon Sculptor II programmers can be chained together using a standard IEEE 1284 parallel port cable.

Table 12-5 • Programming Ordering Codes (continued)

Description	Vendor	Ordering Code	Comment
Concurrent programming cable	Actel	SS-EXPANDER	Used to cascade Silicon Sculptor I programmers together*
Software for Silicon Sculptor	Actel	SCULPTOR-SOFTWARE-CD	http://www.actel.com/download/program_debug/ss/
ISP cable for small header	Actel	ISP-CABLE-S	Supplied with SMPA-ISP-ACTEL-3-KIT
ISP cable for large header	Actel	PA-ISP-CABLE	Supplied with SMPA-ISP-ACTEL-3-KIT
Header converter	Actel	Header-Converter	Converts from small to large header
Small programming header	Samtec	FTSH-113-01-L-D-K	Supported by FlashPro, FlashPro Lite, and Silicon Sculptor In migrating to ProASIC3/E devices, an FP3-26PIN-ADAPTER is required.
10-pin 0.1" pitch cable header (right-angle PCB mount angle)	AMP	103310-1	Supported by FlashPro3
10-pin 0.1" pitch cable header (straight PCB mount angle)	3M	2510-6002UB	Supported by FlashPro3
Compact programming header (10-pin 0.05" pitch, 2 rows of 5 pins)	Samtec	FTSH-105-01-L-D-K	Supported by FlashPro3, FP3-10PIN-ADAPTER-KIT required. Used for boards where space is at a premium.
Migration and compact header adapter	Actel	FP3-10PIN-ADAPTER-KIT	Compact header and migration kit. Comes with Samtec FFSD-05-D-06.00-01-N (6-inch cable for connecting to compact 10-pin headers).
Large programming header, 0.062" board thickness	3M	3429-6502	Supported by Silicon Sculptor by default, FlashPro and FlashPro Lite with header converter
Large programming header, 0.094" to 0.125" board thickness	3M	3429-6503	Supported by Silicon Sculptor by default, FlashPro and FlashPro Lite with header converter
Plug-in header, small	Actel	SMPA-ISP-HEADER-S	Required for small header for ProASIC only; not used for ProASIC ^{PLUS}
Plug-in header	Actel	SMPA-ISP-HEADER	Required for large header for ProASIC only; not used for ProASIC ^{PLUS}
Vacuum pens for PQ, TQ, VQ; <208 pins	Actel	PENVAC	
Vacuum pens for PQ, TQ, VQ; ≥208 pins	Actel	PENVAC-HD	Heavy-duty, provides stronger vacuum

* A maximum of two Silicon Sculptor II programmers can be chained together using a standard IEEE 1284 parallel port cable.

Programmer Device Support

Refer to [Table 12-6](#) to determine which general-purpose flash devices have programmer device support. To learn more about the different Actel families, refer to the Actel website:

<http://www.actel.com/products/devices.aspx>.

Data in [Table 12-6](#) also applies to ARM-enabled M7 device versions of Fusion, IGLOO, and ProASIC3 devices. Refer to the appropriate family datasheets for information on die/package combinations available as ARM-enabled versions.

Table 12-6 • Programmer Device Support

Actel Family	Device	ARM-Enabled	Silicon Sculptor	Silicon Sculptor 6X	Silicon Sculptor II	Silicon Sculptor 3	FlashPro	FlashPro Lite	FlashPro3
Fusion	AFS090		No	No	Yes. No ISP support.	Yes. No ISP support.	No	No	Yes. ISP support

* Refer to the "Certified Programming Solutions" section on page 12-12 for more information on programmer support.

Certified Programming Solutions

The Actel-certified programmers for flash devices are FlashPro3, FlashPro Lite, FlashPro, Silicon Sculptor I and II, and any programmer that is built by BP Microsystems. All other programmers are considered noncertified programmers.

- **FlashPro3, FlashPro Lite, FlashPro**

The Actel family of FlashPro device programmers provides in-system programming in an easy-to-use, compact system that supports all flash families. Whether programming a board containing a single device or multiple devices connected in a chain, the Actel line of FlashPro programmers enables fast programming and reprogramming. Programming with the FlashPro series of programmers saves board space and money as it eliminates the need for sockets on the board. There are no built-in algorithms, so there is no delay between product release and programming support.

- **Silicon Sculptor II**

Silicon Sculptor II is a robust, compact, single-device programmer with standalone software for the PC. It is designed to enable concurrent programming of multiple units from the same PC with speeds equivalent to or faster than previous Actel programmers. It replaces Silicon Sculptor I as the Actel programmer of choice.

- **Silicon Sculptor I and Silicon Sculptor 6X**

Actel no longer offers Silicon Sculptor I or Silicon Sculptor 6X for sale. Both items have been discontinued. Actel does support Silicon Sculptor I and Silicon Sculptor 6X by continuing to release new software that enables improved programming of previously covered Actel devices; new Actel devices are only supported on Silicon Sculptor II. All software support for Silicon Sculptor I and Silicon Sculptor 6X programmers will be discontinued by the end of 2005; no support for these older programmers will be offered in 2006. Actel recommends that all customers upgrade to Silicon Sculptor II or a BP multi-site programmer.

- **Noncertified Programmers**

Actel does not test programming solutions from other vendors, and CANNOT guarantee programming yield. Also, Actel will not perform any failure analysis on devices programmed by hardware from other vendors.

- **Programming Centers**

Actel programming hardware policy also applies to programming centers. Actel expects all programming centers to use certified programmers to program Actel devices. If a programming center uses noncertified programmers to program Actel devices, the "Noncertified Programmers" policy applies.

Flash Programming Guidelines

Preprogramming Setup

Before programming, several steps are required to ensure an optimal programming yield.

Use Proper Handling and Electrostatic Discharge (ESD) Precautions

Actel FPGAs are sensitive electronic devices that are susceptible to damage from ESD and other types of mishandling. For more information about ESD, refer to the [Actel Quality and Reliability Guide](#), beginning with page 41.

Use the Latest Version of the Designer Software to Generate Your Programming File (recommended)

The files used to program Actel flash devices (*.bit, *.stp) contain important information about the switches that will be programmed in the FPGA. Find the latest version and corresponding release notes at <http://www.actel.com/download/software/designer/>. Also, programming files must always be zipped during file transfer to avoid the possibility of file corruption.

Use the Latest Version of the Programming Software

The programming software is frequently updated to accommodate yield enhancements in FPGA manufacturing. These updates ensure maximum programming yield and minimum programming times. Before programming, always check the version of software being used to ensure it is the most recent. Depending on the programming software, refer to one of the following:

- FlashPro: http://www.actel.com/download/program_debug/flashpro/
- Silicon Sculptor: http://www.actel.com/download/program_debug/ss/

Use the Most Recent Adapter Module with Silicon Sculptor

Occasionally, Actel makes modifications to the adapter modules to improve programming yields and programming times. To identify the latest version of each module before programming, visit http://www.actel.com/products/hardware/program_debug/ss/modules.aspx.

Perform Routine Hardware Self-Diagnostic Test

- FlashPro
The self-test is only applicable when programming with FlashPro and FlashPro3 programmers. It is not supported with FlashPro Lite. To run the self-diagnostic test, follow the instructions given in the "Performing a Self-Test" section of http://www.actel.com/documents/FlashPro_UG.pdf.
- Silicon Sculptor
The self-diagnostic test verifies correct operation of the pin drivers, power supply, CPU, memory, and adapter module. This test should be performed before every programming session. At minimum, the test must be executed every week. To perform self-diagnostic testing using the Silicon Sculptor software, perform the following steps, depending on the operating system:
 - DOS: From anywhere in the software, type **ALT + D**.
 - Windows: Click **Device** > choose **Actel Diagnostic** > select the **Test** tab > click **OK**.

Programming Flash FPGAs

Programming a flash device is a one-step process, whether programming is conducted with a socket adapter module or via ISP. The Execute function will automatically erase the device, program the flash cells, and verify that it is programmed correctly. Actel recommends confirming the security status is correct before programming.

The following steps are required to program Actel flash FPGAs.

Programming with FlashPro

Setup

Properly connect the FlashPro ribbon cable with the programming header and turn on the switch. Actel recommends running the self-test before programming any devices; see the "[Perform Routine Hardware Self-Diagnostic Test](#)" section on page 12-13.

In the programming software, from the File menu, choose **Connect**. In the FlashPro Connect to Programmer dialog box that appears, select the port to which the FlashPro programmer is connected, and select the device family. Disable voltages from the programmer if they are available on the board.

Click **Connect**. A successful connect or any errors appear in the Log window.

Analyze Chain and Device Selection

From the File menu, choose **Analyze Chain**. Chain details appear in the Log window. If any failures appear, refer to the error and troubleshooting section of the [FlashPro User's Guide](#). Select the device to be programmed from the **Device** list. If only one device is present in the chain, performing Analyze Chain selects that device automatically from the Device list.

Loading the STAPL file

FlashPro3, FlashPro Lite, and FlashPro programmers use a STAPL (*.stp) file to program the device. To load the STAPL file, from the File menu, choose **Open STAPL file**, or click the **Open File** button on the toolbar.

Selecting an Action

After loading the STAPL file, select an action from the Action list. See the "Programming File Actions" section in the *FlashPro User's Guide* for a definition of each action.

Programming the Device

To program the device, in the Action list, select **Program**. Make the required selections and click **Execute** to start programming. The progress of the programming action displays in the Log window. The message "Exit 0" indicates that the device has successfully been programmed.

Note: Do not interrupt the programming sequence; it may damage the device or programmer.

Verify Correct Programming

To verify the device is programmed with the correct STAPL file, load the STAPL file and in the Action list, click **Verify**. Click **Execute** to start the verification process. A successful verification results in "Exit 0."

Note: Verification is also performed in the previous "Programming the Device" step; clicking **Verify** is an additional standalone option.

Programming Failure Allowances

Flash FPGAs are reprogrammable, so Actel tests the programmability for 100% of the devices shipped.

Return Material Authorization (RMA) Policies

Actel consistently strives to exceed customer expectations by continuing to improve the quality of our products and our quality management system. Actel has RMA procedures in place to address programming fallout. Customers should be mindful of the following RMA policies.

All devices submitted for an RMA must be within the Actel warranty period of one year from date of shipment. Actel will reject RMAs for devices that are no longer under warranty.

RMAs will only be authorized for current Actel devices. Devices that have been discontinued will not receive RMAs. All functional failure analysis requests must be initiated by opening a case with Actel Technical Support. Devices returned for failure analysis against an RMA should be in their original packaging and must have an RMA number issued by Actel.

Contacting the Customer Support Group

Highly skilled engineers staff the Customer Applications Center from 7:00 A.M. to 6:00 P.M., Pacific time, Monday through Friday. You can contact the center by one of the following methods:

Electronic Mail

You can communicate your technical questions to our email address and receive answers back by email, fax, or phone. Also, if you have design problems, you can email your design files to receive assistance. Actel monitors the email account throughout the day. When sending your request to us, please be sure to include your full name, company name, and contact information for efficient processing of your request. The technical support email address is tech@actel.com.

Telephone

Our Technical Support Hotline answers all calls. The center retrieves information, such as your name, company name, telephone number, and question. Once this is done, a case number is assigned. Then the center forwards the information to a queue where the first available applications engineer receives the data and returns your call. The phone hours are from 7:00 A.M. to 6:00 P.M., Pacific time, Monday through Friday.

The Customer Applications Center number is (800) 262-1060.

European customers can call +44 (0) 1256 305 600.

Part Number 51700094-013-3

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.3)	Page
v1.2 (October 2008)	The " Programming Support in Flash Devices " section was updated to include IGLOO nano and ProASIC3 nano devices.	12-2
	The " Flash Devices " section was updated to include information for IGLOO nano devices. The following sentence was added: IGLOO PLUS devices can also be operated at any voltage between 1.2 V and 1.5 V; the Designer software allows 50 mV increments in the voltage.	12-4
	Table 12-5 · Programming Ordering Codes was updated to replace FP3-26PIN-ADAPTER with FP3-10PIN-ADAPTER-KIT.	12-8
	Table 12-6 · Programmer Device Support was updated to add IGLOO nano and ProASIC3 nano devices. AGL400 was added to the IGLOO portion of the table.	12-10
v1.1 (March 2008)	The " Programming Support in Flash Devices " section was revised to include new families and make the information more concise.	12-2
	Figure 12-1 · FlashPro Programming Setup and the " Programming Support in Flash Devices " section are new.	12-1, 12-2
	Table 12-6 · Programmer Device Support was updated to include A3PE600L with the other ProASIC3L devices, and the RT ProASIC3 family was added.	12-10
v1.0 (January 2008)	The " Flash Devices " section was updated to include the IGLOO PLUS family. The text, "Voltage switching is required in-system to switch from a 1.2 V core to 1.5 V core for programming," was revised to state, "Although the device can operate at 1.2 V core voltage, the device can only be reprogrammed when the core voltage is 1.5 V. Voltage switching is required in-system to switch from a 1.2 V supply (V_{CC} , V_{CCI} , and V_{JTAG}) to 1.5 V for programming."	12-4
	The ProASIC3L family was added to Table 12-6 · Programmer Device Support as a separate set of rows rather than combined with ProASIC3 and ProASIC3E devices. The IGLOO PLUS family was included, and AGL015 and A3P015 were added.	12-10

13 – Security in Low-Power Flash Devices

Security in Programmable Logic

The need for security on FPGA programmable logic devices (PLDs) has never been greater than today. If the contents of the FPGA can be read by an external source, the intellectual property (IP) of the system is vulnerable to unauthorized copying. Actel Fusion,® IGLOO,® and ProASIC®3 devices contain state-of-the-art circuitry to make the flash-based devices secure during and after programming. Low-power flash devices have a built-in 128-bit Advanced Encryption Standard (AES) decryption core (except for 30 k gate devices and smaller). The decryption core facilitates secure in-system programming (ISP) of the FPGA core array fabric, the FlashROM, and the Flash Memory Blocks (FBs) in Fusion devices. The FlashROM, Flash Blocks, and FPGA core fabric can be programmed independently of each other, allowing the FlashROM or Flash Blocks to be updated without the need for change to the FPGA core fabric.

Actel has incorporated the AES decryption core into the low-power flash devices and has also included the Actel flash-based lock technology, FlashLock.® Together, they provide leading-edge security in a programmable logic device. Configuration data loaded into a device can be decrypted prior to being written to the FPGA core using the AES 128-bit block cipher standard. The AES encryption key is stored in on-chip, nonvolatile flash memory.

This document outlines the security features offered in low-power flash devices, some applications and uses, as well as the different software settings for each application.

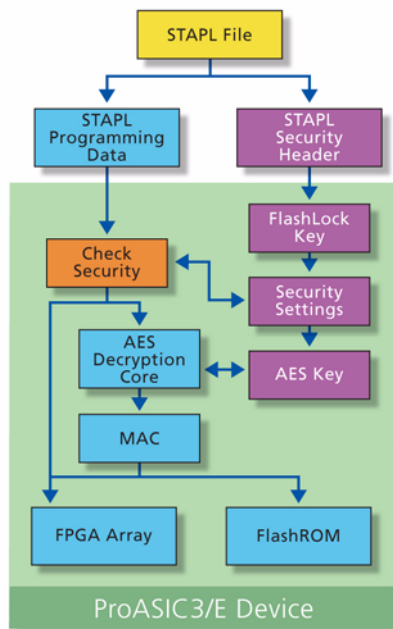

Figure 13-1 • Overview on Security

Security Support in Flash-Based Devices

The flash FPGAs listed in [Table 13-1](#) support the security feature and the functions described in this document.

Table 13-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 13-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 13-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Security Architecture

Fusion, IGLOO, and ProASIC3 devices have been designed with the most comprehensive programming logic design security in the industry. In the architecture of these devices, security has been designed into the very fabric. The flash cells are located beneath seven metal layers, and the use of many device design and layout techniques makes invasive attacks difficult. Since device layers cannot be removed without disturbing the charge on the programmed (or erased) flash gates, devices cannot be easily deconstructed to decode the design. Low-power flash devices are unique in being reprogrammable and having inherent resistance to both invasive and noninvasive attacks on valuable IP. Secure, remote ISP is now possible with AES encryption capability for the programming file during electronic transfer. Figure 13-2 shows a view of the AES decryption core inside an IGLOO device; Figure 13-3 on page 13-4 shows the AES decryption core inside a Fusion device. The AES core is used to decrypt the encrypted programming file when programming.

*Note: *ISP AES Decryption is not supported by 30 k gate devices and smaller. For details of other architecture features by device, refer to the appropriate family datasheet.*

Figure 13-2 • Block Representation of the AES Decryption Core in IGLOO and ProASIC3 Devices

Figure 13-3 • Block Representation of the AES Decryption Core in a Fusion AFS600 FPGA

Security Features

IGLOO and ProASIC3 devices have two entities inside: FlashROM and the FPGA core fabric. Fusion devices contain three entities: FlashROM, FBs, and the FPGA core fabric. The parts can be programmed or updated independently with a STAPL programming file. The programming files can be AES-encrypted or plaintext. This allows maximum flexibility in providing security to the entire device. Refer to *FlashROM in Actel's Low-Power Flash Devices* for information on the FlashROM structure.

Unlike SRAM-based FPGA devices, which require a separate boot PROM to store programming data, low-power flash devices are nonvolatile, and the secured configuration data is stored in on-chip flash cells that are part of the FPGA fabric. Once programmed, this data is an inherent part of the FPGA array and does not need to be loaded at system power-up. SRAM-based FPGAs load the configuration bitstream upon power-up; therefore, the configuration is exposed and can be read easily.

The built-in FPGA core, FBs, and FlashROM support programming files encrypted with the 128-bit AES (FIPS-192) block ciphers. The AES key is stored in dedicated, on-chip flash memory and can be programmed before the device is shipped to other parties (allowing secure remote field updates).

Security in ARM-Enabled Low-Power Flash Devices

There are slight differences between the regular flash devices and the ARM[®]-enabled flash devices, which have the M1 and M7 prefix.

The AES key is used by Actel and preprogrammed into the device to protect the ARM IP. As a result, the design is encrypted along with the ARM IP, according to the details below.

CoreMP7 Device Security

ARM7 (M7-enabled) devices are shipped with the following security features:

- FPGA array enabled for AES-encrypted programming and verification
- FlashROM enabled for plaintext Read and Write

Cortex-M1 Device Security

Cortex-M1-enabled devices are shipped with the following security features:

- FPGA array enabled for AES-encrypted programming and verification
- FlashROM enabled for AES-encrypted Write and Verify
- Fusion Embedded Flash Memory enabled for AES-encrypted Write

AES Encryption of Programming Files

Low-power flash devices employ AES as part of the security mechanism that prevents invasive and noninvasive attacks. The mechanism entails encrypting the programming file with AES encryption and then passing the programming file through the AES decryption core, which is embedded in the device. The file is decrypted there, and the device is successfully programmed. The AES master key is stored in on-chip nonvolatile memory (flash). The AES master key can be preloaded into parts in a secure programming environment (such as the Actel In-House Programming center), and then "blank" parts can be shipped to an untrusted programming or manufacturing center for final personalization with an AES-encrypted bitstream. Late-stage product changes or personalization can be implemented easily and securely by simply sending a STAPL file with AES-encrypted data. Secure remote field updates over public networks (such as the Internet) are possible by sending and programming a STAPL file with AES-encrypted data.

The AES key protects the programming data for file transfer into the device with 128-bit AES encryption. If AES encryption is used, the AES key is stored or preprogrammed into the device. To program, you must use an AES-encrypted file, and the encryption used on the file must match the encryption key already in the device.

The AES key is protected by a FlashLock security Pass Key that is also implemented in each device. The AES key is always protected by the FlashLock Key, and the AES-encrypted file does NOT contain the FlashLock Key. This FlashLock Pass Key technology is exclusive to the Actel flash-based device families. FlashLock Pass Key technology can also be implemented without the AES encryption option, providing a choice of different security levels.

In essence, security features can be categorized into the following three options:

- AES encryption with FlashLock Pass Key protection
- FlashLock protection only (no AES encryption)
- No protection

Each of the above options is explained in more detail in the following sections with application examples and software implementation options.

Advanced Encryption Standard

The 128-bit AES standard (FIPS-192) block cipher is the NIST (National Institute of Standards and Technology) replacement for DES (Data Encryption Standard FIPS46-2). AES has been designed to protect sensitive government information well into the 21st century. It replaces the aging DES, which NIST adopted in 1977 as a Federal Information Processing Standard used by federal agencies to protect sensitive, unclassified information. The 128-bit AES standard has 3.4×10^{38} possible 128-bit key variants, and it has been estimated that it would take 1,000 trillion years to crack 128-bit AES cipher text using exhaustive techniques. Keys are stored (securely) in low-power flash devices in nonvolatile flash memory. All programming files sent to the device can be authenticated by the part prior to programming to ensure that bad programming data is not loaded into the part that may possibly damage it. All programming verification is performed on-chip, ensuring that the contents of low-power flash devices remain secure.

Actel has implemented the 128-bit AES (Rijndael) algorithm in low-power flash devices. With this key size, there are approximately 3.4×10^{38} possible 128-bit keys. DES has a 56-bit key size, which provides approximately 7.2×10^{16} possible keys. In their AES fact sheet, the National Institute of

Standards and Technology uses the following hypothetical example to illustrate the theoretical security provided by AES. If one were to assume that a computing system existed that could recover a DES key in a second, it would take that same machine approximately 149 trillion years to crack a 128-bit AES key. NIST continues to make their point by stating the universe is believed to be less than 20 billion years old.¹

The AES key is securely stored on-chip in dedicated low-power flash device flash memory and cannot be read out. In the first step, the AES key is generated and programmed into the device (for example, at a secure or trusted programming site). The Actel Designer software tool provides AES key generation capability. After the key has been programmed into the device, the device will only correctly decrypt programming files that have been encrypted with the same key. If the individual programming file content is incorrect, a Message Authentication Control (MAC) mechanism inside the device will fail in authenticating the programming file. In other words, when an encrypted programming file is being loaded into a device that has a different programmed AES key, the MAC will prevent this incorrect data from being loaded, preventing possible device damage. See [Figure 13-3 on page 13-4](#) and [Figure 13-4 on page 13-7](#) for graphical representations of this process.

It is important to note that the user decides what level of protection will be implemented for the device. When AES protection is desired, the FlashLock Pass Key must be set. The AES key is a content protection mechanism, whereas the FlashLock Pass Key is a device protection mechanism. When the AES key is programmed into the device, the device still needs the Pass Key to protect the FPGA and FlashROM contents and the security settings, including the AES key. Using the FlashLock Pass Key prevents modification of the design contents by means of simply programming the device with a different AES key.

AES Decryption and MAC Authentication

Low-power flash devices have a built-in 128-bit AES decryption core, which decrypts the encrypted programming file and performs a MAC check that authenticates the file prior to programming.

MAC authenticates the entire programming data stream. After AES decryption, the MAC checks the data to make sure it is valid programming data for the device. This can be done while the device is still operating. If the MAC validates the file, the device will be erased and programmed. If the MAC fails to validate, then the device will continue to operate uninterrupted.

This will ensure the following:

- Correct decryption of the encrypted programming file
- Prevention of erroneous or corrupted data being programmed during the programming file transfer
- Correct bitstream passed to the device for decryption

Figure 13-4 • Example Application Scenario Using AES in IGLOO and ProASIC3 Devices

Figure 13-5 • Example Application Scenario Using AES in Fusion Devices

FlashLock

Additional Options for IGLOO and ProASIC3 Devices

The user also has the option of prohibiting Write operations to the FPGA array but allowing Verify operations on the FPGA array and/or Read operations on the FlashROM without the use of the FlashLock Pass Key. This option provides the user the freedom of verifying the FPGA array and/or reading the FlashROM contents after the device is programmed, without having to provide the FlashLock Pass Key. The user can incorporate AES encryption on the programming files to better enhance the level of security used.

Permanent Security Setting Options

In applications where a permanent lock is not desired, yet the security settings should not be modifiable, IGLOO and ProASIC3 devices can accommodate this requirement.

This application is particularly useful in cases where a device is located at a remote location and must be reprogrammed with a design or data update. Refer to the "[Application 3: Nontrusted Environment—Field Updates/Upgrades](#)" section on page 13-10 for further discussion and examples of how this can be achieved.

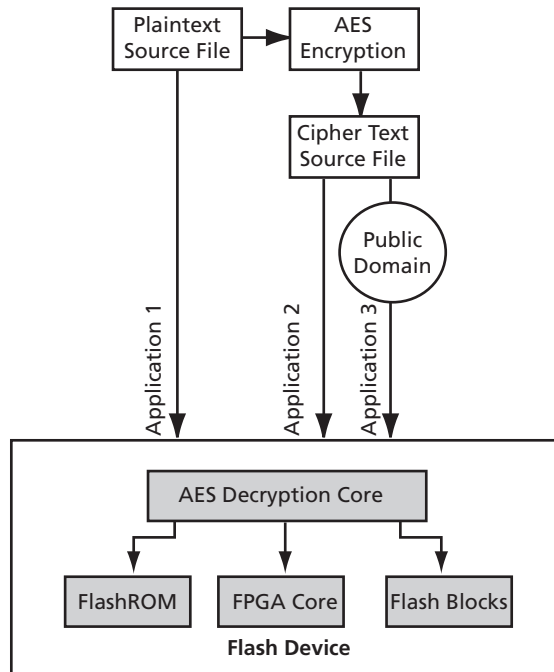

The user must be careful when considering the Permanent FlashLock or Permanent Security Settings option. Once the design is programmed with the permanent settings, it is not possible to reconfigure the security settings already employed on the device. Therefore, exercise careful consideration before programming permanent settings.

Permanent FlashLock

The purpose of the permanent lock feature is to provide the benefits of the highest level of security to IGLOO and ProASIC3 devices. If selected, the permanent FlashLock feature will create a permanent barrier, preventing any access to the contents of the device. This is achieved by permanently disabling Write and Verify access to the array, and Write and Read access to the FlashROM. After permanently locking the device, it has been effectively rendered one-time-programmable. This feature is useful if the intended applications do not require design or system updates to the device.

Security in Action

This section illustrates some applications of the security advantages of Actel's devices ([Figure 13-6](#)).

Note: Flash blocks are only used in Fusion devices.

Figure 13-6 • Security Options

Application 1: Trusted Environment

As illustrated in [Figure 13-7 on page 13-10](#), this application allows the programming of devices at design locations where research and development take place. Therefore, encryption is not necessary and is optional to the user. This is often a secure way to protect the design, since the design program files are not sent elsewhere. In situations where production programming is not available at the design location, programming centers (such as Actel In-House Programming) provide a way of programming designs at an alternative, secure, and trusted location. In this scenario, the user generates a STAPL programming file from the Designer software in plaintext format, containing information on the entire design or the portion of the design to be programmed. The user can choose to employ the FlashLock Pass Key feature with the design. Once the design is programmed to unprogrammed devices, the design is protected by this FlashLock Pass Key. If no future programming is needed, the user can consider permanently securing the IGLOO and ProASIC3 device, as discussed in the "[Permanent FlashLock](#)" section on [page 13-8](#).

Application 2: Nontrusted Environment—Unsecured Location

Often, programming of devices is not performed in the same location as actual design implementation, to reduce manufacturing cost. Overseas programming centers and contract manufacturers are examples of this scenario.

To achieve security in this case, the AES key and the FlashLock Pass Key can be initially programmed in-house (trusted environment). This is done by generating a programming file with only the security settings and no design contents. The design FPGA core, FlashROM, and (for Fusion) FB contents are generated in a separate programming file. This programming file must be set with the same AES key that was used to program to the device previously so the device will correctly decrypt this encrypted programming file. As a result, the encrypted design content programming file can

be safely sent off-site to nontrusted programming locations for design programming. Figure 13-7 shows a more detailed flow for this application.

Notes:

1. Programmed portion indicated with dark gray.
2. Programming of FBs applies to Fusion only.

Figure 13-7 • Application 2: Device Programming in a Nontrusted Environment

Application 3: Nontrusted Environment—Field Updates/Upgrades

Programming or reprogramming of devices may occur at remote locations. Reconfiguration of devices in consumer products/equipment through public networks is one example. Typically, the remote system is already programmed with particular design contents. When design update (FPGA array contents update) and/or data upgrade (FlashROM and/or FB contents upgrade) is necessary, an updated programming file with AES encryption can be generated, sent across public networks, and transmitted to the remote system. Reprogramming can then be done using this AES-encrypted programming file, providing easy and secure field upgrades. Low-power flash devices support this secure ISP using AES. The detailed flow for this application is shown in Figure 13-8 on page 13-11. Refer to *Microprocessor Programming of Actel's Low-Power Flash Devices* for more information.

To prepare devices for this scenario, the user can initially generate a programming file with the available security setting options. This programming file is programmed into the devices before shipment. During the programming file generation step, the user has the option of making the security settings permanent or not. In situations where no changes to the security settings are necessary, the user can select this feature in the software to generate the programming file with permanent security settings. Actel recommends that the programming file use encryption with an AES key, especially when ISP is done via public domain.

For example, if the designer wants to use an AES key for the FPGA array and the FlashROM, **Permanent** needs to be chosen for this setting. At first, the user chooses the options to use an AES key for the FPGA array and the FlashROM, and then chooses **Permanently lock the security settings**. A unique AES key is chosen. Once this programming file is generated and programmed to

the devices, the AES key is permanently stored in the on-chip memory, where it is secured safely. The devices are sent to distant locations for the intended application. When an update is needed, a new programming file must be generated. The programming file must use the same AES key for encryption; otherwise, the authentication will fail and the file will not be programmed in the device.

Figure 13-8 • Application 3: Nontrusted Environment—Field Updates/Upgrades

FlashROM Security Use Models

Each of the subsequent sections describes in detail the available selections in Actel Designer as an aid to understanding security applications and generating appropriate programming files for those applications. Before proceeding, it is helpful to review [Figure 13-7 on page 13-10](#), which gives a general overview of the programming file generation flow within the Designer software as well as what occurs during the device programming stage. Specific settings are discussed in the following sections.

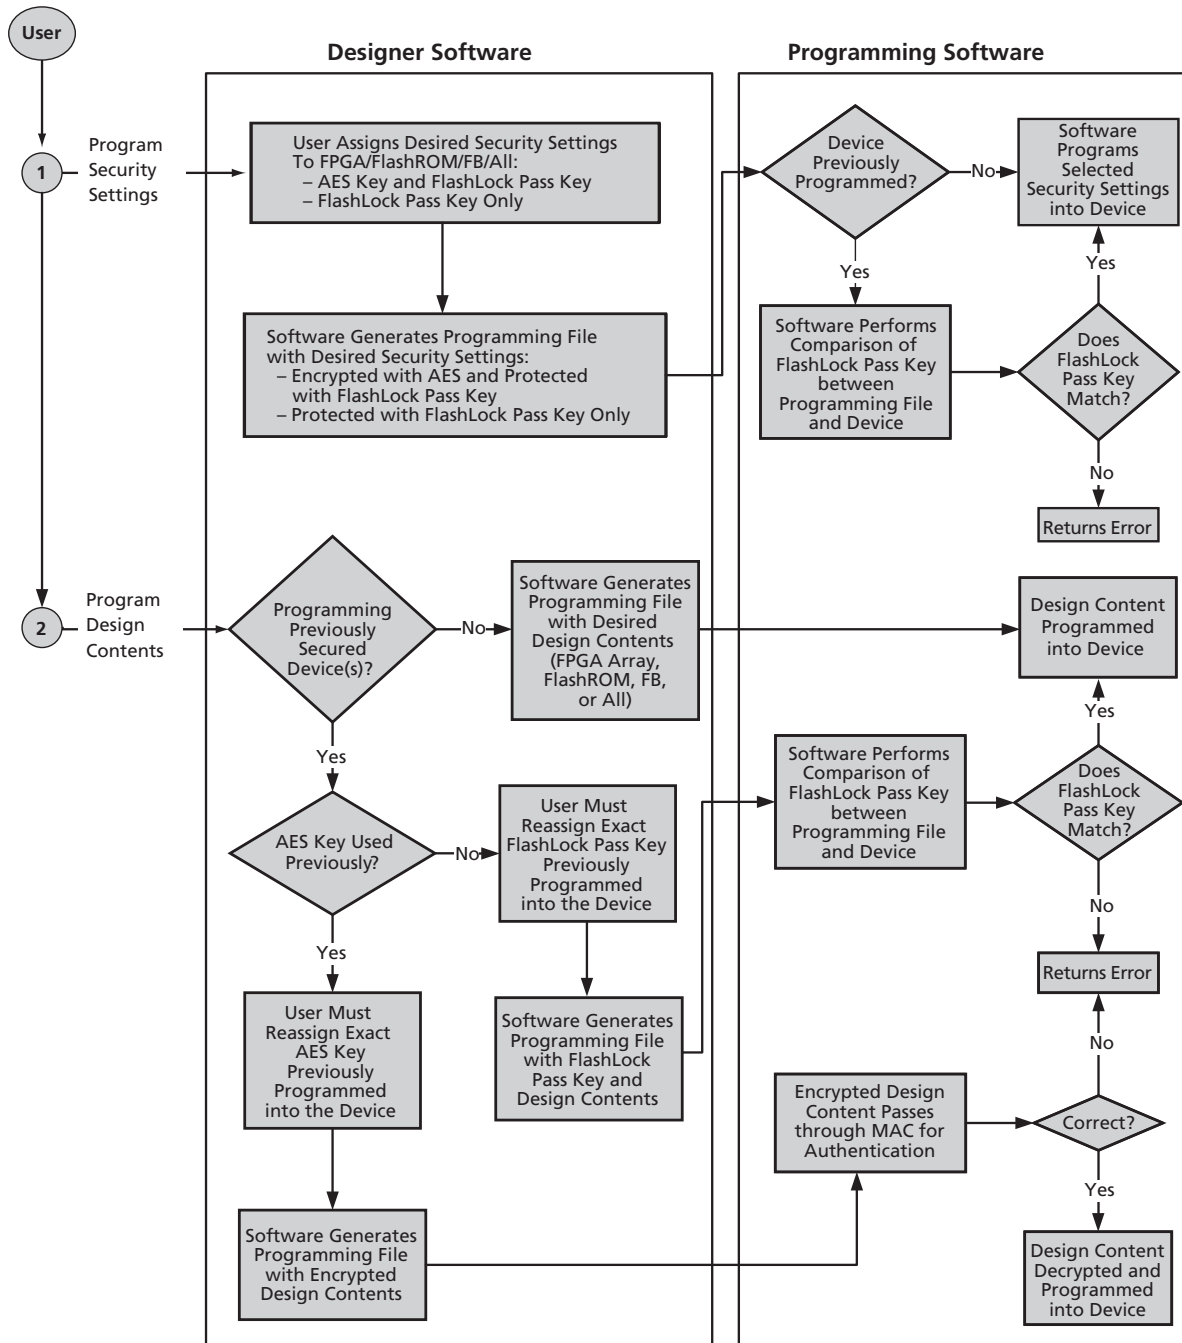

In [Figure 13-7 on page 13-10](#), the flow consists of two sub-flows. Sub-flow 1 describes programming security settings to the device only, and sub-flow 2 describes programming the design contents only.

In Application 1, described in the "[Application 1: Trusted Environment](#)" section on page 13-9, the user does not need to generate separate files but can generate one programming file containing both security settings and design contents. Then programming of the security settings and design contents is done in one step. Both sub-flow 1 and sub-flow 2 are used.

In Application 2, described in the "[Application 2: Nontrusted Environment—Unsecured Location](#)" section on page 13-9, the trusted site should follow sub-flows 1 and 2 separately to generate two separate programming files. The programming file from sub-flow 1 will be used at the trusted site to program the device(s) first. The programming file from sub-flow 2 will be sent off-site for production programming.

In Application 3, described in the "Application 3: Nontrusted Environment—Field Updates/Upgrades" section on page 13-10, typically only sub-flow 2 will be used, because only updates to the design content portion are needed and no security settings need to be changed.

In the event that update of the security settings is necessary, see the "Reprogramming Devices" section on page 13-21 for details. For more information on programming low-power flash devices, refer to *In-System Programming (ISP) of Actel's Low-Power Flash Devices Using FlashPro3*.

Note: If programming the Security Header only, just perform sub-flow 1.
If programming design content only, just perform sub-flow 2.

Figure 13-9 • Security Programming Flows

Generating Programming Files

Generation of the Programming File in a Trusted Environment— Application 1

As discussed in the "Application 1: Trusted Environment" section on page 13-9, in a trusted environment, the user can choose to program the device with plaintext bitstream content. It is possible to use plaintext for programming even when the FlashLock Pass Key option has been selected. In this application, it is not necessary to employ AES encryption protection. For AES encryption settings, refer to the next sections.

The generated programming file will include the security setting (if selected) and the plaintext programming file content for the FPGA array, FlashROM, and/or FBs. These options are indicated in Table 13-2 and Table 13-3.

Table 13-2 • IGLOO and ProASIC3 Plaintext Security Options, No AES

Security Protection	FlashROM Only	FPGA Core Only	Both FlashROM and FPGA
No AES / no FlashLock	✓	✓	✓
FlashLock only	✓	✓	✓
AES and FlashLock	–	–	–

Table 13-3 • Fusion Plaintext Security Options

Security Protection	FlashROM Only	FPGA Core Only	FB Core Only	All
No AES / no FlashLock	✓	✓	✓	✓
FlashLock	✓	✓	✓	✓
AES and FlashLock	–	–	–	–

Note: For all instructions, the programming of Flash Blocks refers to Fusion only.

For this scenario, generate the programming file as follows:

1. Select the **Silicon features to be programmed** (Security Settings, FPGA Array, FlashROM, Flash Memory Blocks), as shown in Figure 13-10 on page 13-14 and Figure 13-11 on page 13-14. Click **Next**.

If **Security Settings** is selected (i.e., the FlashLock security Pass Key feature), an additional dialog will be displayed to prompt you to select the security level setting. If no security setting is selected, you will be directed to Step 3.

Figure 13-10 • All Silicon Features Selected for IGLOO and ProASIC3 Devices

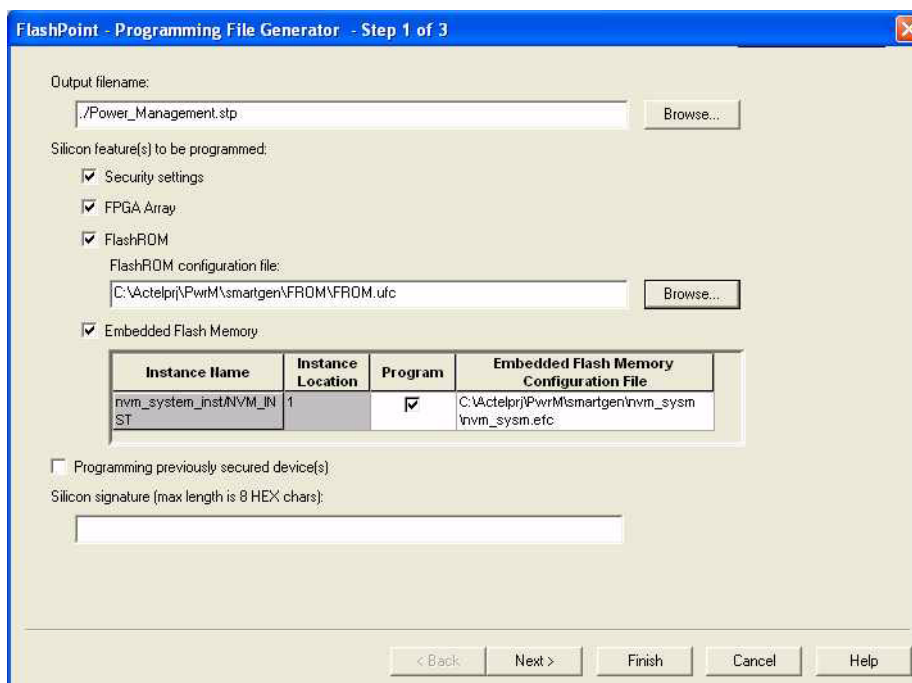

Figure 13-11 • All Silicon Features Selected for Fusion

2. Choose the appropriate security level setting and enter a FlashLock Pass Key. The default is the **Medium** security level (Figure 13-12). Click **Next**.

If you want to select different options for the FPGA and/or FlashROM, this can be set by clicking **Custom Level**. Refer to the "Advanced Options" section on page 13-22 for different custom security level options and descriptions of each.

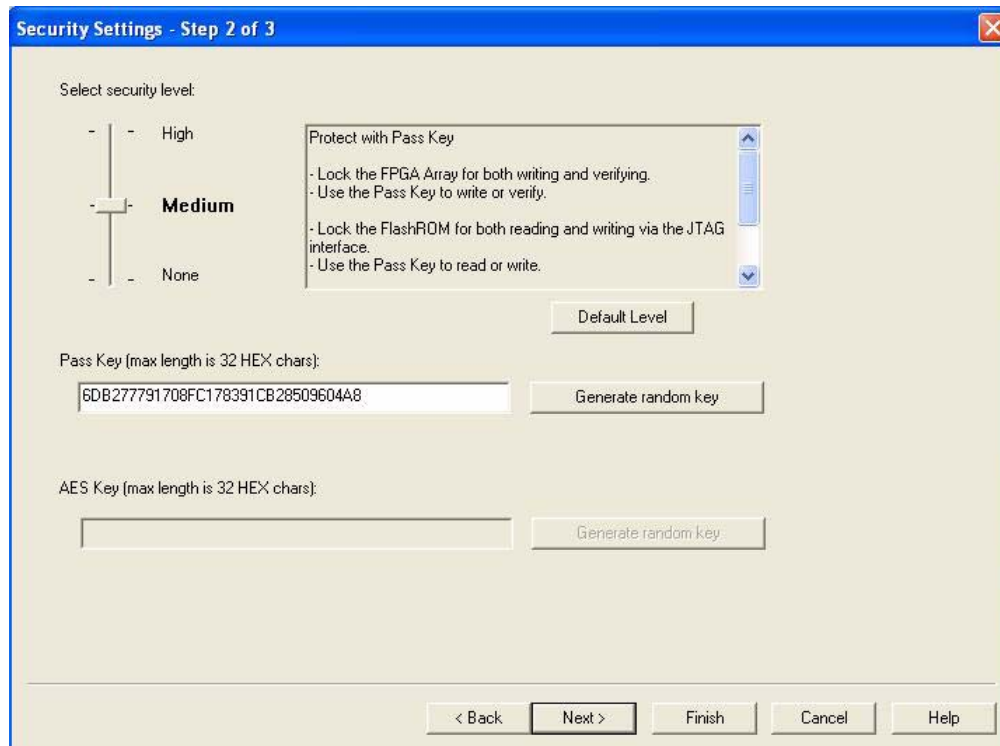

Figure 13-12 • Medium Security Level Selected for Low-Power Flash Devices

- Choose the desired settings for the FlashROM configurations to be programmed (Figure 13-13). Click **Finish** to generate the STAPL programming file for the design.

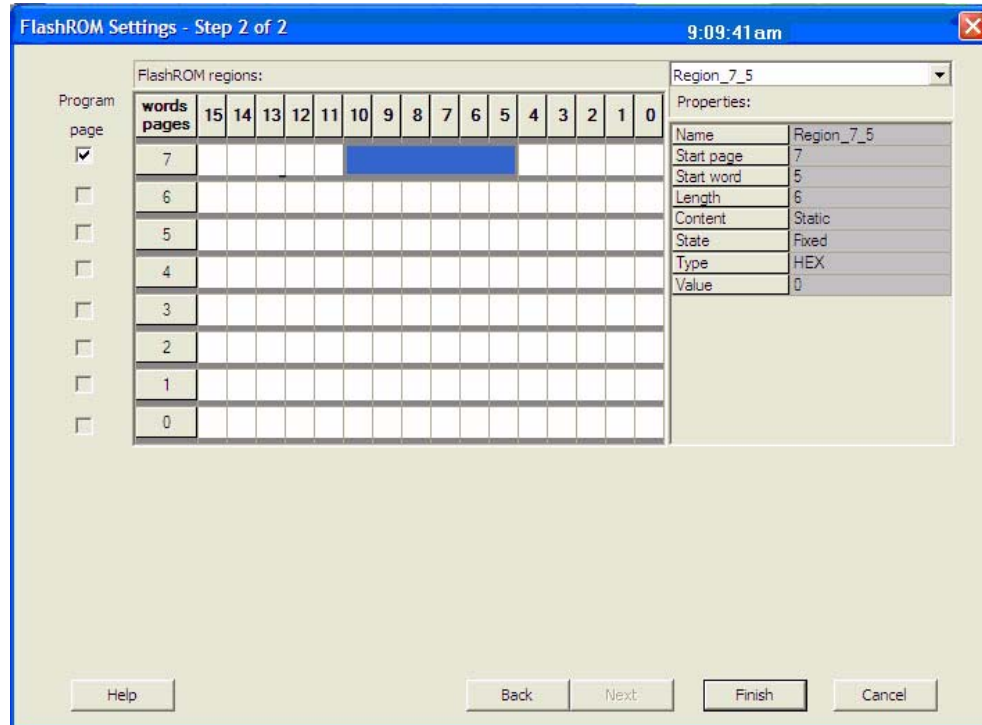

Figure 13-13 • FlashROM Configuration Settings for Low-Power Flash Devices

Generation of Security Header Programming File Only— Application 2

As mentioned in the "Application 2: Nontrusted Environment—Unsecured Location" section on page 13-9, the designer may employ FlashLock Pass Key protection or FlashLock Pass Key with AES encryption on the device before sending it to a nontrusted or unsecured location for device programming. To achieve this, the user needs to generate a programming file containing only the security settings desired (Security Header programming file).

Note: If AES encryption is configured, FlashLock Pass Key protection must also be configured.

The available security options are indicated in Table 13-4 and Table 13-5 on page 13-17.

Table 13-4 • FlashLock Security Options for IGLOO and ProASIC3

Security Option	FlashROM Only	FPGA Core Only	Both FlashROM and FPGA
No AES / no FlashLock	–	–	–
FlashLock only	✓	✓	✓
AES and FlashLock	✓	✓	✓

Table 13-5 • FlashLock Security Options for Fusion

Security Option	FlashROM Only	FPGA Core Only	FB Core Only	All
No AES / no FlashLock	–	–	–	–
FlashLock	✓	✓	✓	✓
AES and FlashLock	✓	✓	✓	✓

For this scenario, generate the programming file as follows:

1. Select only the **Security settings** option, as indicated in Figure 13-14 and Figure 13-15 on page 13-18. Click **Next**.

Figure 13-14 • Programming IGLOO and ProASIC3 Security Settings Only

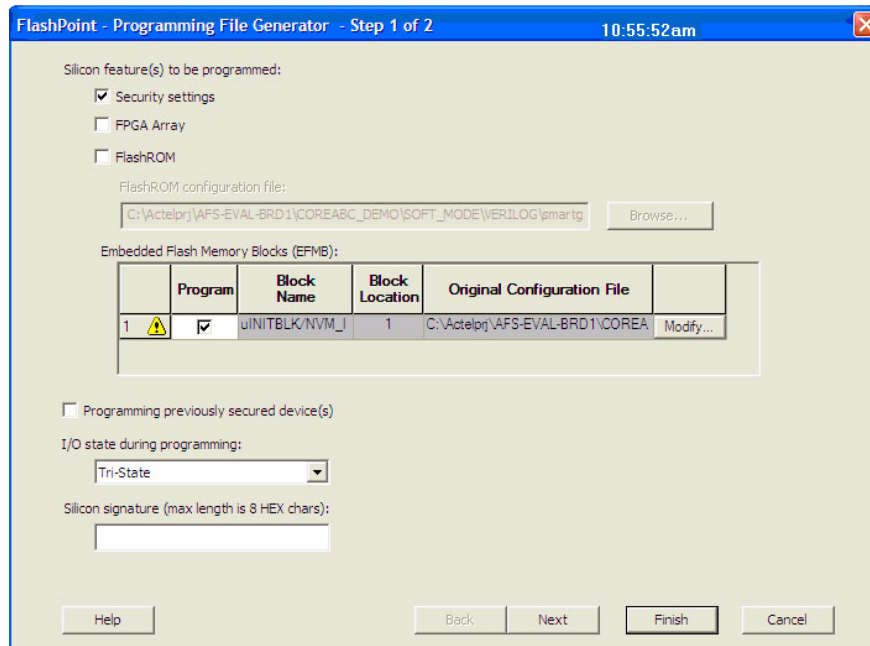

Figure 13-15 • Programming Fusion Security Settings Only

2. Choose the desired security level setting and enter the key(s).
 - The **High** security level employs FlashLock Pass Key with AES Key protection.
 - The **Medium** security level employs FlashLock Pass Key protection only.

Figure 13-16 • High Security Level to Implement FlashLock Pass Key and AES Key Protection

Table 13-6 and Table 13-7 show all available options. If you want to implement custom levels, refer to the "Advanced Options" section on page 13-22 for information on each option and how to set it.

- When done, click **Finish** to generate the Security Header programming file.

Table 13-6 • All IGLOO and ProASIC3 Header File Security Options

Security Option	FlashROM Only	FPGA Core Only	Both FlashROM and FPGA
No AES / no FlashLock	✓	✓	✓
FlashLock only	✓	✓	✓
AES and FlashLock	✓	✓	✓

Note: ✓ = options that may be used

Table 13-7 • All Fusion Header File Security Options

Security Option	FlashROM Only	FPGA Core Only	FB Core Only	All
No AES / No FlashLock	✓	✓	✓	✓
FlashLock	✓	✓	✓	✓
AES and FlashLock	✓	✓	✓	✓

Generation of Programming Files with AES Encryption— Application 3

This section discusses how to generate design content programming files needed specifically at unsecured or remote locations to program devices with a Security Header (FlashLock Pass Key and AES key) already programmed ("Application 2: Nontrusted Environment—Unsecured Location" section on page 13-9 and "Application 3: Nontrusted Environment—Field Updates/Upgrades" section on page 13-10). In this case, the encrypted programming file must correspond to the AES key already programmed into the device. If AES encryption was previously selected to encrypt the FlashROM, FBs, and FPGA array, AES encryption must be set when generating the programming file for them. AES encryption can be applied to the FlashROM only, the FBs only, the FPGA array only, or all. The user must ensure both the FlashLock Pass Key and the AES key match those already programmed to the device(s), and all security settings must match what was previously programmed. Otherwise, the encryption and/or device unlocking will not be recognized when attempting to program the device with the programming file.

The generated programming file will be AES-encrypted.

In this scenario, generate the programming file as follows:

- Deselect **Security settings** and select the portion of the device to be programmed (Figure 13-17 on page 13-20). Select **Programming previously secured device(s)**. Click **Next**.

Note: The settings in this figure are used to show the generation of an AES-encrypted programming file for the FPGA array, FlashROM, and FB contents. One or all locations may be selected for encryption.

Figure 13-17 • Settings to Program a Device Secured with FlashLock and using AES Encryption

Choose the **High** security level to reprogram devices using both the FlashLock Pass Key and AES key protection (Figure 13-18 on page 13-21). Enter the AES key and click **Next**.

A device that has already been secured with FlashLock and has an AES key loaded must recognize the AES key to program the device and generate a valid bitstream in authentication. The FlashLock Key is only required to unlock the device and change the security settings.

This is what makes it possible to program in an untrusted environment. The AES key is protected inside the device by the FlashLock Key, so you can only program if you have the correct AES key. In fact, the AES key is not in the programming file either. It is the key used to encrypt the data in the file. The same key previously programmed with the FlashLock Key matches to decrypt the file.

An AES-encrypted file programmed to a device without FlashLock would not be secure, since without FlashLock to protect the AES key, someone could simply reprogram the AES key first, then program with any AES key desired or no AES key at all. This option is therefore not available in the software.

Figure 13-18 • Security Level Set High to Reprogram Device with AES Key

Programming with this file is intended for an unsecured environment. The AES key encrypts the programming file with the same AES key already used in the device and utilizes it to program the device.

Reprogramming Devices

Previously programmed devices can be reprogrammed using the steps in the "Generation of the Programming File in a Trusted Environment—Application 1" section on page 13-13 and "Generation of Security Header Programming File Only—Application 2" section on page 13-16. In the case where a FlashLock Pass Key has been programmed previously, the user must generate the new programming file with a FlashLock Pass Key that matches the one previously programmed into the device. The software will check the FlashLock Pass Key in the programming file against the FlashLock Pass Key in the device. The keys must match before the device can be unlocked to perform further programming with the new programming file.

Figure 13-10 on page 13-14 and Figure 13-11 on page 13-14 show the option **Programming previously secured device(s)**, which the user should select before proceeding. Upon going to the next step, the user will be notified that the same FlashLock Pass Key needs to be entered, as shown in Figure 13-19 on page 13-22.

Figure 13-19 • FlashLock Pass Key, Previously Programmed Devices

It is important to note that when the security settings need to be updated, the user also needs to select the **Security settings** check box in Step 1, as shown in [Figure 13-10 on page 13-14](#) and [Figure 13-11 on page 13-14](#), to modify the security settings. The user must consider the following:

- If only a new AES key is necessary, the user must re-enter the same Pass Key previously programmed into the device in Designer and then generate a programming file with the same Pass Key and a different AES key. This ensures the programming file can be used to access and program the device and the new AES key.
- If a new Pass Key is necessary, the user can generate a new programming file with a new Pass Key (with the same or a new AES key if desired). However, for programming, the user must first load the original programming file with the Pass Key that was previously used to unlock the device. Then the new programming file can be used to program the new security settings.

Advanced Options

As mentioned, there may be applications where more complicated security settings are required. The “Custom Security Levels” section in the *FlashPro User's Guide* describes different advanced options available to aid the user in obtaining the best available security settings.

Programming File Header Definition

In each STAPL programming file generated, there will be information about how the AES key and FlashLock Pass Key are configured. Table 13-8 shows the header definitions in STAPL programming files for different security levels.

Table 13-8 • STAPL Programming File Header Definitions by Security Level

Security Level	STAPL File Header Definition
No security (no FlashLock Pass Key or AES key)	NOTE "SECURITY" "Disable";
FlashLock Pass Key with no AES key	NOTE "SECURITY" "KEYED ";
FlashLock Pass Key with AES key	NOTE "SECURITY" "KEYED ENCRYPT ";
Permanent Security Settings option enabled	NOTE "SECURITY" "PERMLOCK ENCRYPT ";
AES-encrypted FPGA array (for programming updates)	NOTE "SECURITY" "ENCRYPT CORE ";
AES-encrypted FlashROM (for programming updates)	NOTE "SECURITY" "ENCRYPT FROM ";
AES-encrypted FPGA array and FlashROM (for programming updates)	NOTE "SECURITY" "ENCRYPT FROM CORE ";

Conclusion

The new and enhanced security features offered in Actel Fusion, IGLOO, and ProASIC3 devices provide state-of-the-art security to designs programmed into these flash-based devices. Actel low-power flash devices employ the encryption standard used by NIST and the U.S. government—AES using the 128-bit Rijndael algorithm.

The combination of an on-chip AES decryption engine and Actel FlashLock technology provides the highest level of security against invasive attacks and design theft, implementing the most robust and secure ISP solution. These security features protect IP within the FPGA and protect the system from cloning, wholesale “black box” copying of a design, invasive attacks, and explicit IP or data theft.

Glossary

Term	Explanation
Security Header programming file	Programming file used to program the FlashLock Pass Key and/or AES key into the device to secure the FPGA, FlashROM, and/or FBs.
AES (encryption) key	128-bit key defined by the user when the AES encryption option is set in the Actel Designer software when generating the programming file.
FlashLock Pass Key	128-bit key defined by the user when the FlashLock option is set in the Actel Designer software when generating the programming file. The FlashLock Key protects the security settings programmed to the device. Once a device is programmed with FlashLock, whatever settings were chosen at that time are secure.
FlashLock	The combined security features that protect the device content from attacks. These features are the following: <ul style="list-style-type: none"> • Flash technology that does not require an external bitstream to program the device • FlashLock Pass Key that secures device content by locking the security settings and preventing access to the device as defined by the user • AES key that allows secure, encrypted device reprogrammability

Part Number and Revision Date

This document contains content extracted from the Device Architecture section of the datasheet, combined with content previously published as an application note describing features and functions of the device. To improve usability for customers, the device architecture information has now been combined with usage information, to reduce duplication and possible inconsistencies in published information. No technical changes were made to the datasheet content unless explicitly listed. Changes to the application note content were made only to be consistent with existing datasheet information.

Part Number 51700094-014-4

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 13-1 · Flash-Based FPGAs .	13-2
v1.2 (June 2008)	The " Security Support in Flash-Based Devices " section was revised to include new families and make the information more concise.	13-2
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 13-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> • ProASIC3L was updated to include 1.5 V. • The number of PLLs for ProASIC3E was changed from five to six. 	13-2
v1.0 (January 2008)	The chapter was updated to include the IGLOO PLUS family and information regarding 15 k gate devices.	N/A
	The " IGLOO Terminology " section and " ProASIC3 Terminology " section are new.	13-2

14 – In-System Programming (ISP) of Actel’s Low-Power Flash Devices Using FlashPro3

Introduction

Actel's low-power flash devices are all in-system programmable. This document describes the general requirements for programming a device and specific requirements for the FlashPro3 programmer.

Fusion, IGLOO,® and ProASIC®3 devices offer a low-power, single-chip, live-at-power-up solution with the ASIC advantages of security and low unit cost through nonvolatile flash technology. Each device contains 1 kbit of on-chip, user-accessible, nonvolatile FlashROM. The FlashROM can be used in diverse system applications such as Internet Protocol (IP) addressing, user system preference storage, device serialization, or subscription-based business models. Fusion, IGLOO, and ProASIC3 devices offer the best in-system programming (ISP) solution, FlashLock® security features, and AES-decryption-based ISP.

ISP Architecture

Low-power flash devices support ISP via JTAG and require a single V_{PUMP} voltage of 3.3 V during programming. In addition, programming via a microcontroller in a target system is also supported.

Refer to *Microprocessor Programming of Actel's Low-Power Flash Devices*.

Family-specific support:

- Fusion, ProASIC3, and ProASIC3E devices support ISP.
- ProASIC3L devices operate using a 1.2 V core voltage and support ISP at 1.5 V only. Voltage switching is required in-system to switch from a 1.2 V core to 1.5 V core for programming.
- IGLOO and IGLOOe V5 devices can be programmed in-system when the device is using a 1.5 V supply voltage to the FPGA core.
- All IGLOO V2 and ProASIC3L devices can be operated at any voltage between 1.2 V and 1.5 V. Designer software allows 50 mV increments in the voltage. Although devices can operate at 1.2 V core voltage, a device can only be reprogrammed when the core voltage is 1.5 V. Voltage switching is required in-system to switch from a 1.2 V supply (V_{CC} , V_{CC1} , and V_{JTAG}) to 1.5 V for programming.

IGLOO devices cannot be programmed in-system when the device is in Flash*Freeze mode. The device should exit Flash*Freeze mode and be in normal operation for programming to start. Programming operations in IGLOO devices can be achieved when the device is in normal operating mode and a 1.5 V core voltage is used.

JTAG 1532

Fusion, IGLOO, and ProASIC3 devices support the JTAG-based IEEE 1532 standard for ISP. To start JTAG operations, the IGLOO device should exit Flash*Freeze mode and be in normal operation before starting to send JTAG commands to the device. As part of this support, when a device is in an unprogrammed state, all user I/O pins are disabled. This is achieved by keeping the global IO_EN signal deactivated, which also has the effect of disabling the input buffers. The SAMPLE/PRELOAD instruction captures the status of pads in parallel and shifts them out as new data is shifted in for loading into the Boundary Scan Register (BSR). When the device is in an unprogrammed state, the SAMPLE/PRELOAD instruction has no effect on I/O status; however, it will continue to shift in new data to be loaded into the BSR. Therefore, when SAMPLE/PRELOAD is used on an unprogrammed device, the BSR will be loaded with undefined data. For JTAG timing information on setup, hold, and fall times, refer to the *FlashPro User's Guide*.

ISP Support in Flash-Based Devices

The flash FPGAs listed in [Table 14-1](#) support the ISP feature and the functions described in this document.

Table 14-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 14-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 14-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Programming Voltage (V_{PUMP}) and V_{JTAG}

Low-power flash devices support on-chip charge pumps, and therefore require only a single 3.3 V programming voltage for the V_{PUMP} pin during programming. When the device is not being programmed, the V_{PUMP} pin can be left floating or can be tied (pulled up) to any voltage between 0 V and 3.6 V. During programming, the target board or the FlashPro3 programmer can provide V_{PUMP} . FlashPro3 is capable of supplying V_{PUMP} to a single device. If more than one device is to be programmed using FlashPro3 on a given board, FlashPro3 should not be relied on to supply the V_{PUMP} voltage.

Low-power flash device I/Os support a bank-based, voltage-supply architecture that simultaneously supports multiple I/O voltage standards (Table 14-2 on page 14-3). By isolating the JTAG power supply in a separate bank from the user I/Os, low-power flash devices provide greater flexibility with supply selection and simplify power supply and printed circuit board (PCB) design. The JTAG pins can be run at any voltage from 1.5 V to 3.3 V (nominal). Actel recommends that TCK be tied to GND or V_{JTAG} when not used. This prevents a possible totempole current on the input buffer stage. For TDI, TMS, and TRST pins, the devices provide an internal nominal 10 k Ω pull-up resistor. During programming, all I/O pins, except for JTAG interface pins, are tristated and weakly pulled up to V_{CCI} . This isolates the part and prevents the signals from floating. The JTAG interface pins are driven by the FlashPro3 during programming, including the TRST pin, which is driven HIGH.

Table 14-2 • Power Supplies

Power Supply	Programming Mode	Current during Programming
V_{CC}	1.5 V	< 70 mA
V_{CCI}	1.5 V / 1.8 V / 2.5 V / 3.3 V (bank-selectable)	I/Os are weakly pulled up.
V_{JTAG}	1.5 V / 1.8 V / 2.5 V / 3.3 V	< 20 mA
V_{PUMP}	3.0 V to 3.6 V	< 80 mA

Note: All supply voltages should be at 1.5 V or higher, regardless of the setting during normal operation.

IEEE 1532 (JTAG) Interface

The supported industry-standard IEEE 1532 programming interface builds on the IEEE 1149.1 (JTAG) standard. IEEE 1532 defines the standardized process and methodology for ISP. Both silicon and software issues are addressed in IEEE 1532 to create a simplified ISP environment. Any IEEE 1532-compliant programmer can be used to program low-power flash devices. However, only limited security and FlashROM features are supported when using the IEEE 1532 standard. The Actel FlashPro3 programmer was developed exclusively for these devices and will support all the security and device serialization features. Refer to the standard for detailed information about IEEE 1532.

Security

Unlike SRAM-based FPGAs that require loading at power-up from an external source such as a microcontroller or boot PROM, Actel nonvolatile devices are live at power-up, and there is no bitstream required to load the device when power is applied. The unique flash-based architecture prevents reverse engineering of the programmed code on the device, because the programmed data is stored in nonvolatile memory cells. Each nonvolatile memory cell is made up of small capacitors and any physical deconstruction of the device will disrupt stored electrical charges.

Each low-power flash device has a built-in 128-bit Advanced Encryption Standard (AES) decryption core, except for the 30 k gate devices and smaller. Any FPGA core or FlashROM content loaded into the device can optionally be sent as encrypted bitstream and decrypted as it is loaded. This is

particularly suitable for applications where device updates must be transmitted over an unsecured network such as the Internet. The embedded AES decryption core can prevent sensitive data from being intercepted (Figure 14-1 on page 14-4). A single 128-bit AES Key (32 hex characters) is used to encrypt FPGA core programming data and/or FlashROM programming data in the Actel tools. The low-power flash devices also decrypt with a single 128-bit AES Key. In addition, low-power flash devices support a Message Authentication Code (MAC) for authentication of the encrypted bitstream on-chip. This allows the encrypted bitstream to be authenticated and prevents erroneous data from being programmed into the device. The FPGA core, FlashROM, and Flash Memory Blocks (FBs), in Fusion only, can be updated independently using a programming file that is AES-encrypted (cipher text) or uses plain text.

Security in ARM-Enabled Low-Power Flash Devices

There are slight differences between the regular flash device and the ARM®-enabled flash devices, which have the M1 and M7 prefix.

The AES key is used by Actel and preprogrammed into the device to protect the ARM IP. As a result, the design will be encrypted along with the ARM IP, according to the details below.

CoreMP7 Device Security

ARM7™ (M7-enabled) devices are shipped with the following security features:

- FPGA array enabled for AES encrypted programming and verification
- FlashROM enabled for plaintext read and write

Cortex-M1 Device Security

Cortex-M1-enabled devices are shipped with the following security features:

- FPGA array enabled for AES-encrypted programming and verification
- FlashROM enabled for AES-encrypted write and verify
- Fusion Embedded Flash Memory enabled for AES encrypted write

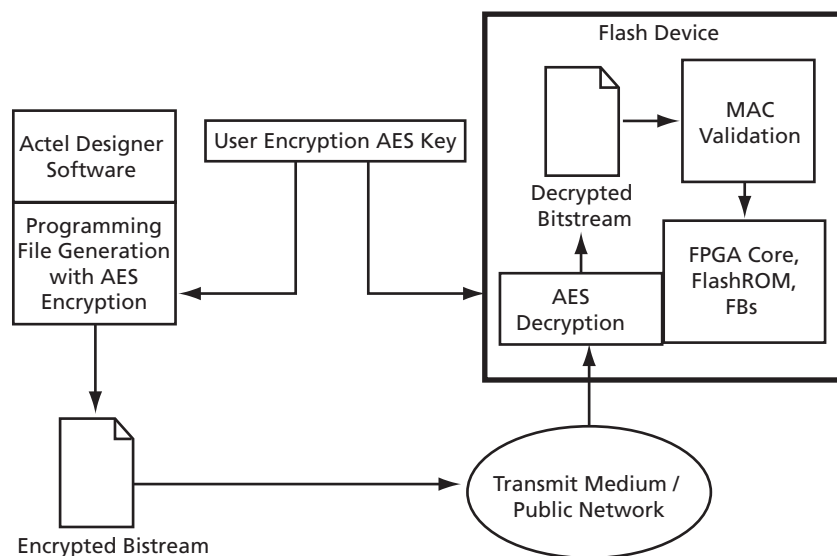

Figure 14-1 • AES-128 Security Features

Figure 14-2 shows different applications for ISP programming.

1. In a trusted programming environment, you can program the device using the unencrypted (plaintext) programming file.
2. You can program the AES Key in a trusted programming environment and finish the final programming in an untrusted environment using the AES-encrypted (cipher text) programming file.
3. For the remote ISP updating/reprogramming, the AES Key stored in the device enables the encrypted programming bitstream to be transmitted through the untrusted network connection.

Actel low-power flash devices also provide the unique Actel FlashLock feature, which protects the Pass Key and AES Key. Unless the original FlashLock Pass Key is used to unlock the device, security settings cannot be modified. Low-power flash devices do not support read-back of FPGA core-programmed data; however, the FlashROM contents can selectively be read back (or disabled) via the JTAG port based on the security settings established by the Actel Designer software. Refer to [Security in Low-Power Flash Devices](#) for more information.

Figure 14-2 • Different ISP Use Models

FlashROM and Programming Files

Each low-power flash device has 1 kbit of on-chip, nonvolatile flash memory that can be accessed from the FPGA core. This nonvolatile FlashROM is arranged in eight pages of 128 bits (Figure 14-3). Each page can be programmed independently, with or without the 128-bit AES encryption. The FlashROM can only be programmed via the IEEE 1532 JTAG port and cannot be programmed from the FPGA core. In addition, during programming of the FlashROM, the FPGA core is powered down automatically by the on-chip programming control logic.

	3																
	2																
	1																
	0																

Figure 14-3 • FlashROM Architecture

Using FlashROM combined with AES, many subscription-based applications or device serialization applications are possible. SmartGen supports easy management of the FlashROM contents even over large numbers of devices. SmartGen can support FlashROM contents that contain the following:

- Static values
- Random numbers
- Values read from a file
- Independent updates of each page

In addition, auto-incrementing of fields is possible. In applications where the FlashROM content is different for each device, you have the option to generate a single STAPL file for all the devices or individual serialization files for each device. For more information on how to generate the FlashROM content for device serialization, refer to *FlashROM in Actel's Low-Power Flash Devices*.

Actel Libero® Integrated Designed Environment (IDE) includes a unique tool to support the generation and management of FlashROM and FPGA programming files. This tool is called FlashPoint.

Depending on the applications, designers can use the FlashPoint software to generate a STAPL file with different contents. In each case, optional AES encryption and/or different security settings can be set.

In Designer, when you click the Programming File icon, FlashPoint launches, and you can generate STAPL file(s) with four different cases (Figure 14-4 on page 14-7). When the serialization feature is used during the configuration of FlashROM in SmartGen, you can generate a single STAPL file that will program all the devices or an individual STAPL file for each device.

The following cases present the FPGA core and FlashROM programming file combinations that can be used for different applications. In each case, you can set the optional security settings (FlashLock Pass Key and/or AES Key) depending on the application.

1. A single STAPL file or multiple STAPL files with multiple FlashROM contents and the FPGA core content. A single STAPL file will be generated if the device serialization feature is not used. You can program the whole FlashROM or selectively program individual pages.
2. A single STAPL file for the FPGA core content

3. A single STAPL file or multiple STAPL files with multiple FlashROM contents. A single STAPL file will be generated if the device serialization feature is not used. You can program the whole FlashROM or selectively program individual pages.
4. A single STAPL file to configure the security settings for the device, such as the AES Key and/or Pass Key.

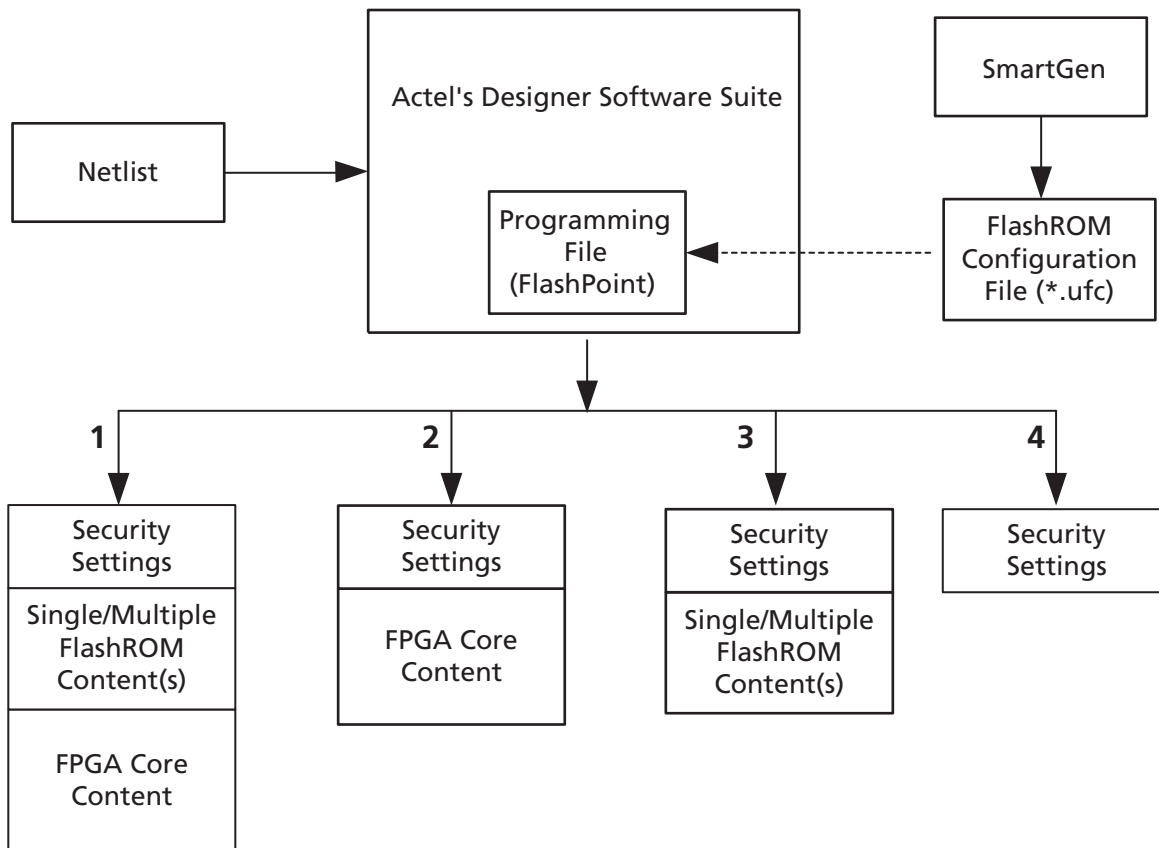

Figure 14-4 • Flexible Programming File Generation for Different Applications

Programming Solution

For device programming, any IEEE 1532-compliant programmer can be used; however, the FlashPro3 programmer must be used to control the low-power flash device's rich security features and FlashROM programming options. The FlashPro3 programmer is a low-cost portable programmer for the Actel flash families. It can also be used with a powered USB hub for parallel programming. General specifications for the FlashPro3 programmer are as follows:

- Programming clock – TCK is used with a maximum frequency of 20 MHz, and the default frequency is 4 MHz.
- Programming file – STAPL
- Daisy chain – Supported. You can use the ChainBuilder software to build the programming file for the chain.
- Parallel programming – Supported. Multiple FlashPro3 programmers can be connected together using a powered USB hub or through the multiple USB ports on the PC.
- Power supply – The target board must provide V_{CC} , V_{CCI} , V_{PUMP} and V_{JTAG} during programming. However, if there is only one device on the target board, the FlashPro3 programmer can generate the required V_{PUMP} voltage from the USB port.

ISP Programming Header Information

The FlashPro3 programming cable connector can be connected with a 10-pin, 0.1"-pitch programming header. The recommended programming headers are manufactured by AMP (103310-1) and 3M (2510-6002UB). If you have limited board space, you can use a compact programming header manufactured by Samtec (FTSH-105-01-L-D-K). Using this compact programming header, you are required to order an additional header adapter manufactured by Actel (FP3-26PIN-ADAPTER).

Existing ProASIC^{PLUS} family customers who are using the Samtec Small Programming Header (FTSH-113-01-L-D-K) and are planning to migrate to IGLOO or ProASIC3 devices can order a separate adapter kit from Actel (FP3-10PIN-ADAPTER-KIT), which contains a compact 10-pin adapter kit as well as 26-pin migration capability.

Table 14-3 • Programming Header Ordering Codes

Manufacturer	Part Number	Description
AMP	103310-1	10-pin, 0.1"-pitch cable header (right-angle PCB mount angle)
3M	2510-6002UB	10-pin, 0.1"-pitch cable header (straight PCB mount angle)
Samtec	FTSH-113-01-L-D-K	Small programming header supported by FlashPro and Silicon Sculptor
Samtec	FTSH-105-01-L-D-K	Compact programming header
Samtec	FFSD-05-D-06.00-01-N	10-pin cable with 50 mil pitch sockets; included in FP3-10PIN-ADAPTER-KIT.
Actel	FP3-10PIN-ADAPTER-KIT	Compact header and migration kit

Figure 14-5 • Programming Header (top view)

Table 14-4 • Programming Header Pin Numbers and Description

Pin	Signal	Source	Description
1	TCK	Programmer	JTAG Clock
2	GND ¹	–	Signal Reference
3	TDO	Target Board	Test Data Output
4	NC	–	No Connect
5	TMS	Programmer	Test Mode Select
6	V _{JTAG}	Target Board	JTAG Supply Voltage
7	V _{PUMP} ²	Programmer/Target Board	Programming Supply Voltage
8	nTRST	Programmer	JTAG Test Reset (Hi-Z with 10 kΩ pull-down, HIGH, LOW, or toggling)
9	TDI	Programmer	Test Data Input
10	GND ¹	–	Signal Reference

Notes:

1. Both GND pins must be connected.
2. FlashPro3 can provide V_{PUMP} if there is only one device on the target board.

Board-Level Considerations

A bypass capacitor is required from V_{PUMP} to GND for all low-power flash devices during programming. This bypass capacitor protects the devices from voltage spikes that may occur on the V_{PUMP} supplies during the erase and programming cycles. Refer to [Pin Descriptions](#) for specific recommendations. For proper programming, 0.01 μF and 0.33 μF capacitors (both rated at 16 V) are to be connected in parallel across V_{PUMP} and GND, and positioned as close to the FPGA pins as possible. The bypass capacitor must be placed within 2.5 cm of the device pins.

Figure 14-6 • Board Layout and Programming Header Top View

Troubleshooting Signal Integrity

Symptoms of a Signal Integrity Problem

A signal integrity problem can manifest itself in many ways. The problem may show up as extra or dropped bits during serial communication, changing the meaning of the communication. There is a normal variation of threshold voltage and frequency response between parts even from the same lot. Because of this, the effects of signal integrity may not always affect different devices on the same board in the same way. Sometimes, replacing a device appears to make signal integrity problems go away, but this is just masking the problem. Different parts on identical boards will exhibit the same problem sooner or later. It is important to fix signal integrity problems early. Unless the signal integrity problems are severe enough to completely block all communication between the device and the programmer, they may show up as subtle problems. Some of the FlashPro3 exit codes that are caused by signal integrity problems are listed below. Signal integrity problems are not the only possible cause of these errors, but this list is intended to show where problems can occur. FlashPro3 allows TCK to be lowered from 24 MHz down to 1 MHz to allow you to address some signal integrity problems that may occur with impedance mismatching at higher frequencies.

Chain Integrity Test Error or Analyze Chain Failure

Normally, the FlashPro3 Analyze Chain command expects to see 0x2 on the TDO pin. If the command reports reading 0x0 or 0x3, it is seeing the TDO pin stuck at 0 or 1. The only time the TDO

pin comes out of tristate is when the JTAG TAP state machine is in the Shift-IR or Shift-DR state. If noise or reflections on the TCK or TMS lines have disrupted the correct state transitions, the device's TAP state controller might not be in one of these two states when the programmer tries to read the device. When this happens, the output is floating when it is read and does not match the expected data value. This can also be caused by a broken TDO net. Only a small amount of data is read from the device during the Analyze Chain command, so marginal problems may not always show up during this command.

Exit 11

This error occurs during the verify stage of programming a device. After programming the design into the device, the device is verified to ensure it is programmed correctly. The verification is done by shifting the programming data into the device. An internal comparison is performed within the device to verify that all switches are programmed correctly. Noise induced by poor signal integrity can disrupt the writes and reads or the verification process and produce a verification error. While technically a verification error, the root cause is often related to signal integrity.

Refer to the *FlashPro User's Guide* for other error messages and solutions. For the most up-to-date known issues and solutions, refer to <http://www.actel.com/support>.

Conclusion

Fusion, IGLOO, and ProASIC3 devices offer a low-cost, single-chip solution that is live at power-up through nonvolatile flash technology. The FlashLock Pass Key and 128-bit AES Key security features enable secure ISP in an untrusted environment. On-chip FlashROM enables a host of new applications, including device serialization, subscription-based applications, and IP addressing. Additionally, as the FlashROM is nonvolatile, all of these services can be provided without battery backup.

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	The "ISP Architecture" section was revised to include information about core voltage for IGLOO V2 and ProASIC3L devices, as well as 50 mV increments allowable in Designer software.	14-1
	IGLOO nano and ProASIC3 nano devices were added to Table 14-1 · Flash-Based FPGAs.	14-2
	A second capacitor was added to Figure 14-6 · Board Layout and Programming Header Top View.	14-9
v1.2 (June 2008)	The "ISP Support in Flash-Based Devices" section was revised to include new families and make the information more concise.	14-2
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 14-1 · Flash-Based FPGAs: <ul style="list-style-type: none"> ProASIC3L was updated to include 1.5 V. The number of PLLs for ProASIC3E was changed from five to six. 	14-2
v1.0 (January 2008)	The "ISP Architecture" section was updated to included the IGLOO PLUS family in the discussion of family-specific support. The text, "When 1.2 V is used, the device can be reprogrammed in-system at 1.5 V only," was revised to state, "Although the device can operate at 1.2 V core voltage, the device can only be reprogrammed when all supplies (V_{CC} , V_{CCI} , and V_{JTAG}) are at 1.5 V."	14-1
	The "ISP Support in Flash-Based Devices" section and Table 14-1 · Flash-Based FPGAs were updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "ProASIC3 Terminology" section are new.	14-2
	The "Security" section was updated to mention that 15 k gate devices do not have a built-in 128-bit decryption core.	14-3
	Table 14-2 · Power Supplies was revised to remove the Normal Operation column and add a table note stating, "All supply voltages should be at 1.5 V or higher, regardless of the setting during normal operation."	14-3
	The "ISP Programming Header Information" section was revised to change FP3-26PIN-ADAPTER to FP3-10PIN-ADAPTER-KIT. Table 14-3 · Programming Header Ordering Codes was updated with the same change, as well as adding the part number FFSD-05-D-06.00-01-N, a 10-pin cable with 50-mil-pitch sockets.	14-8
	The "Board-Level Considerations" section was updated to describe connecting two capacitors in parallel across V_{PUMP} and GND for proper programming.	14-9
51900055-2/7.06	Information was added to the "Programming Voltage (VPUMP) and VJTAG" section about the JTAG interface pin.	14-3

15 – Core Voltage Switching Circuit for IGLOO and ProASIC3L In-System Programming

Introduction

The IGLOO® and ProASIC®3L families offer devices that can be powered by either 1.5 V or, in the case of V2 devices, a core supply voltage anywhere in the range of 1.2 V to 1.5 V, in 50 mV increments.

Since IGLOO and ProASIC3L devices are flash-based, they can be programmed and reprogrammed multiple times in-system using Actel FlashPro3. Actel FlashPro3 uses the JTAG standard interface (IEEE 1149.1) and STAPL file (defined in JESD 71 to support programming of programmable devices using IEEE 1149.1) for in-system configuration/programming (IEEE 1532) of a device. Programming can also be executed by other methods, such as an embedded microcontroller that follows the same standards above.

All IGLOO and ProASIC3L devices must be programmed with the V_{CC} core voltage at 1.5 V. Therefore, applications using IGLOO or ProASIC3L devices powered by a 1.2 V supply must switch the core supply to 1.5 V for in-system programming.

The purpose of this document is to describe an easy-to-use and cost-effective solution for switching the core supply voltage from 1.2 V to 1.5 V during in-system programming for IGLOO and ProASIC3L devices.

Actel's Flash Families Support Voltage Switching Circuit

The flash FPGAs listed in [Table 15-1](#) support the voltage switching circuit feature and the functions described in this document.

Table 15-1 • Flash-Based FPGAs Supporting Voltage Switching Circuit

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 15-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 15-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Circuit Description

All IGLOO devices as well as the ProASIC3L product family are available in two versions: V5 devices, which are powered by a 1.5 V supply and V2 devices, which are powered by a supply anywhere in the range of 1.2 V to 1.5 V in 50 mV increments. Applications that use IGLOO or ProASIC3L devices powered by a 1.2 V core supply must have a mechanism that switches the core voltage from 1.2 V (or other voltage below 1.5 V) to 1.5 V during in-system programming (ISP). There are several possible techniques to meet this requirement. Actel recommends utilizing a linear voltage regulator, a resistor voltage divider, and an N-Channel Digital FET to set the appropriate V_{CC} voltage, as shown in Figure 15-1.

Where 1.2 V is mentioned in the following text, the meaning applies to any voltage below the 1.5 V range. Resistor values in the figures have been calculated for 1.2 V, so refer to power regulator datasheets if a different core voltage is required.

The main component of Actel's recommended circuit is the LTC3025 linear voltage regulator from LinearTech. The output voltage of the LTC3025 on the OUT pin is set by the ratio of two external resistors, R37 and R38, in a voltage divider. The linear voltage regulator adjusts the voltage on the OUT pin to maintain the ADJ pin voltage at 0.4 V (referenced to ground). By using an R38 value of 40.2 k Ω and an R37 value of 80.6 k Ω , the output voltage on the OUT pin is 1.2 V. To achieve 1.5 V on the OUT pin, R44 can be used in parallel with R38. The OUT pin can now be used as a switchable source for the V_{CC} supply. Refer to the *LTC3025 Linear Voltage Regulator datasheet* for more information.

In Figure 15-1, the N-Channel Digital FET is used to enable and disable R44. This FET is controlled by the JTAG TRST signal driven by the FlashPro3 programmer. During programming of the device, the TRST signal is driven HIGH by the FlashPro3, and turns the N-Channel Digital FET ON. When the FET is ON, R44 becomes enabled as a parallel resistance to R38, which forces the regulator to set OUT to 1.5 V.

When the FlashPro3 is connected and not in programming mode or when it is not connected, the pull-down resistor, R10, will pull the TRST signal LOW. When this signal is LOW, the N-Channel Digital FET is "open" and R44 is not part of the resistance seen by the LTC3025. The new resistance momentarily changes the voltage value on the ADJ pin, which in turn causes the output of the LTC3025 to compensate by setting OUT to 1.2 V. Now the device will run in regular active mode at the regular 1.2 V core voltage.

Figure 15-1 • Circuit Diagram

Circuit Verification

The power switching circuit recommended above is implemented on Actel's Icicle board (Figure 15-2). On the Icicle board, VJTAGENB is used to control the N-Channel Digital FET; however, this circuit was modified to use TRST instead of VJTAGENB in this application. There are three important aspects of this circuit that were verified:

1. The rise on V_{CC} from 1.2 V to 1.5 V when TRST is HIGH
2. V_{CC} rises to 1.5 V before programming begins.
3. V_{CC} switches from 1.5 V to 1.2 V when TRST is LOW.

Verification Steps

1. The rise on V_{CC} from 1.2 V to 1.5 V when TRST is HIGH.

Figure 15-2 • Core Voltage on the IGLOO AGL125-QNG132 Device

In the oscilloscope plots (Figure 15-2), the TRST from FlashPro3 and the V_{CC} core voltage of the IGLOO device are labeled. This plot shows the rise characteristic of the TRST signal from FlashPro3. Once the TRST signal is asserted HIGH, the LTC3025 shown in Figure 15-1 on page 15-3 senses the increase in voltage and changes the output from 1.2 V to 1.5 V. It takes the circuit approximately 100 μ s to respond to TRST and change the voltage to 1.5 V on the V_{CC} core.

- V_{CC} rises to 1.5 V before programming begins.

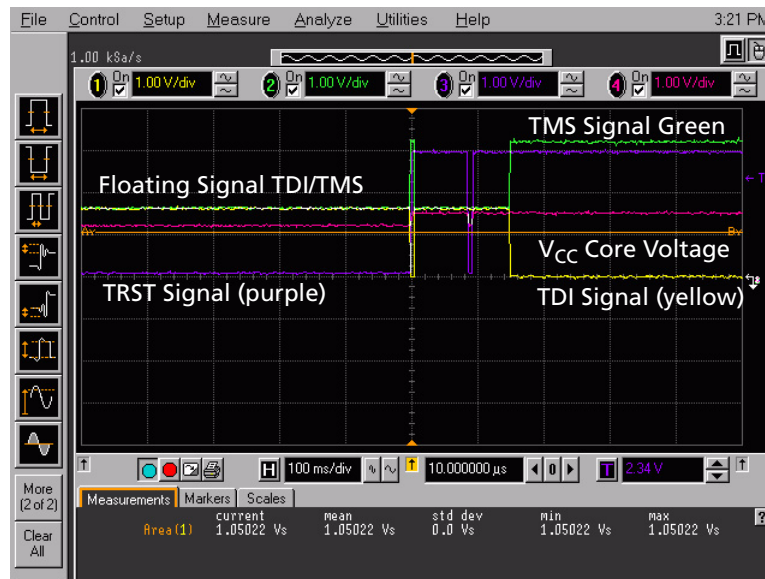

Figure 15-3 • Programming Algorithm

The oscilloscope plot in [Figure 15-3](#) shows a wider time interval for the programming algorithm and includes the TDI and TMS signals from the FlashPro3. These signals carry the programming information that is programmed into the device and should only start toggling after the V_{CC} core voltage reaches 1.5 V. Again, TRST from FlashPro3 and the V_{CC} core voltage of the IGLOO device are labeled. As shown in [Figure 15-3](#), TDI and TMS are floating initially, and the core voltage is 1.2 V. When a programming command on the FlashPro3 is executed, TRST is driven HIGH and TDI is momentarily driven to ground. In response to the HIGH TRST signal, the circuit responds and pulls the core voltage to 1.5 V. After 100 ms, TRST is briefly driven LOW by the FlashPro software. This is expected behavior that ensures the device JTAG state machine is in Reset prior to programming. TRST remains HIGH for the duration of the programming. It can be seen in [Figure 15-3](#) that the V_{CC} core voltage signal remains at 1.5 V for approximately 50 ms before information starts passing through on TDI and TMS. This confirms that the voltage switching circuit drives the V_{CC} core supply voltage to 1.5 V prior to programming.

3. V_{CC} switches from 1.5 V to 1.2 V when TRST is LOW.

Figure 15-4 • TRST Toggled LOW

In [Figure 15-4](#), the TRST signal and the V_{CC} core voltage signal are labeled. As TRST is pulled to ground, the core voltage is observed to switch from 1.5 V to 1.2 V. The observed fall time is approximately 2 ms.

DirectC

The above analysis is based on FlashPro3, but there are other solutions to ISP, such as DirectC. DirectC is a microprocessor program that can be run in-system to program Actel flash devices. For FlashPro3, TRST is the most convenient control signal to use for the recommended circuit. However, for DirectC, users may use any signal to control the FET. For example, the DirectC code can be edited so that a separate non-JTAG signal can be asserted from the microcontroller that signals the board that it is about to start programming the device. After asserting the N-Channel Digital FET control signal, the programming algorithm must allow sufficient time for the supply to rise to 1.5 V before initiating DirectC programming. As seen in [Figure 15-3 on page 15-5](#), 50 ms is adequate time. Depending on the size of the PCB and the capacitance on the V_{CC} supply, results may vary from system to system. Actel recommends using a conservative value for the wait time to make sure that the V_{CC} core voltage is at the right level.

Conclusion

For applications using Actel's IGLOO and ProASIC3L low-power FPGAs and taking advantage of the low core voltage power supplies with less than 1.5 V operation, there must be a way for the core voltage to switch from 1.2 V (or other voltage) to 1.5 V, which is required during in-system programming. The circuit explained in this document illustrates one simple, cost-effective way of handling this requirement. A JTAG signal from the FlashPro3 programmer allows the circuit to sense when programming is in progress, enabling it to switch to the correct core voltage.

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.2)	Page
v1.1 (October 2008)	The " Introduction " was revised to include information about the core supply voltage range of operation in V2 devices.	15-1
	IGLOO nano device support was added to Table 15-1 · Flash-Based FPGAs Supporting Voltage Switching Circuit .	15-2
	The " Circuit Description " section was updated to include IGLOO PLUS core operation from 1.2 V to 1.5 V in 50 mV increments.	15-3
v1.0 (August 2008)	The " Actel's Flash Families Support Voltage Switching Circuit " section was revised to include new families and make the information more concise.	15-2

16 – Microprocessor Programming of Actel’s Low-Power Flash Devices

Introduction

The Fusion, IGLOO,® and ProASIC®3 families of flash FPGAs support in-system programming (ISP) with the use of a microprocessor. Flash-based FPGAs store their configuration information in the actual cells within the FPGA fabric. SRAM-based devices need an external configuration memory, and hybrid nonvolatile devices store the configuration in a flash memory inside the same package as the SRAM FPGA. Since the programming of a true flash FPGA is simpler, requiring only one stage, it makes sense that programming with a microprocessor in-system should be simpler than with other SRAM FPGAs. This reduces bill-of-materials costs and printed circuit board (PCB) area, and increases system reliability.

Nonvolatile flash technology also gives the low-power flash devices the advantage of a secure, low-power, live-at-power-up, and single-chip solution. Low-power flash devices are reprogrammable and offer time-to-market benefits at an ASIC-level unit cost. These features enable engineers to create high-density systems using existing ASIC or FPGA design flows and tools.

This document is an introduction to microprocessor programming only. To explain the difference between the options available, user’s guides for DirectC and STAPL provide more detail on implementing each style.

Figure 16-1 • ISP Using Microprocessor

Microprocessor Programming Support in Flash Devices

The flash-based FPGAs listed in [Table 16-1](#) support programming with a microprocessor and the functions described in this document.

Table 16-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 16-1](#). Where the information applies to only one device or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 16-1](#). Where the information applies to only one device or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Programming Algorithm

JTAG Interface

The low-power flash families are fully compliant with the IEEE 1149.1 (JTAG) standard. They support all the mandatory boundary scan instructions (EXTEST, SAMPLE/PRELOAD, and BYPASS) as well as six optional public instructions (USERCODE, IDCODE, HIGHZ, and CLAMP).

IEEE 1532

The low-power flash families are also fully compliant with the IEEE 1532 programming standard. The IEEE 1532 standard adds programming instructions and associated data registers to devices that comply with the IEEE 1149.1 standard (JTAG). These instructions and registers extend the capabilities of the IEEE 1149.1 standard such that the Test Access Port (TAP) can be used for configuration activities. The IEEE 1532 standard greatly simplifies the programming algorithm, reducing the amount of time needed to implement microprocessor ISP.

Implementation Overview

To implement device programming with a microprocessor, the user should first download the C-based STAPL player or DirectC code from the [Actel website](#). (See the Actel website for future updates regarding the STAPL player and DirectC code). Using the easy-to-follow Actel user's guide, create the low-level application programming interface (API) to provide the necessary basic functions. These API functions act as the interface between the programming software and the actual hardware ([Figure 16-2](#)).

Figure 16-2 • Device Programming Code Relationship

The API is then linked with the STAPL player or DirectC and compiled using the microprocessor's compiler. Once the entire code is compiled, the user must download the resulting binary into the MCU system's program memory (such as ROM, EEPROM, or flash). The system is now ready for programming.

To program a design into the FPGA, the user creates a bitstream or STAPL file using the Actel Designer software, downloads it into the MCU system's volatile memory, and activates the stored programming binary file ([Figure 16-3 on page 16-4](#)). Once the programming is completed, the bitstream or STAPL file can be removed from the system, as the configuration profile is stored in the flash FPGA fabric and does not need to be reloaded at every system power-on.

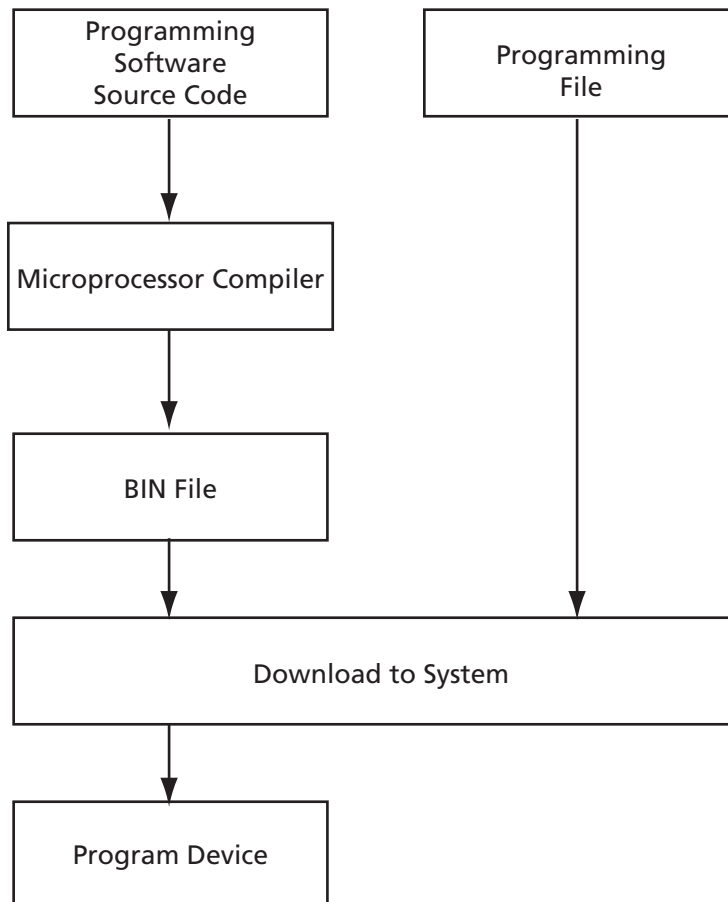

Figure 16-3 • MCU FPGA Programming Model

FlashROM

Actel low-power flash devices have 1 kbit of user-accessible, nonvolatile, FlashROM on-chip. This nonvolatile FlashROM can be programmed along with the core or on its own using the standard IEEE 1532 JTAG programming interface.

The FlashROM is architected as eight pages of 128 bits. Each page can be individually programmed (erased and written). Additionally, on-chip AES security decryption can be used selectively to load data securely into the FlashROM (e.g., over public or private networks, such as the Internet). Refer to *FlashROM in Actel's Low-Power Flash Devices*.

STAPL vs. DirectC

Programming the low-power flash devices is performed using DirectC or the STAPL player. Both tools use the STAPL file as an input. DirectC is a compiled language, whereas STAPL is an interpreted language. Microprocessors will be able to load the FPGA using DirectC much more quickly than STAPL. This speed advantage becomes more apparent when lower clock speeds of 8- or 16-bit microprocessors are used. DirectC also requires less memory than STAPL, since the programming algorithm is directly implemented. STAPL does have one advantage over DirectC—the ability to upgrade. When a new programming algorithm is required, the STAPL user simply needs to regenerate a STAPL file using the latest version of the Designer software and download it to the system. The DirectC user must download the latest version of DirectC from Actel, compile everything, and download the result into the system (Figure 16-4).

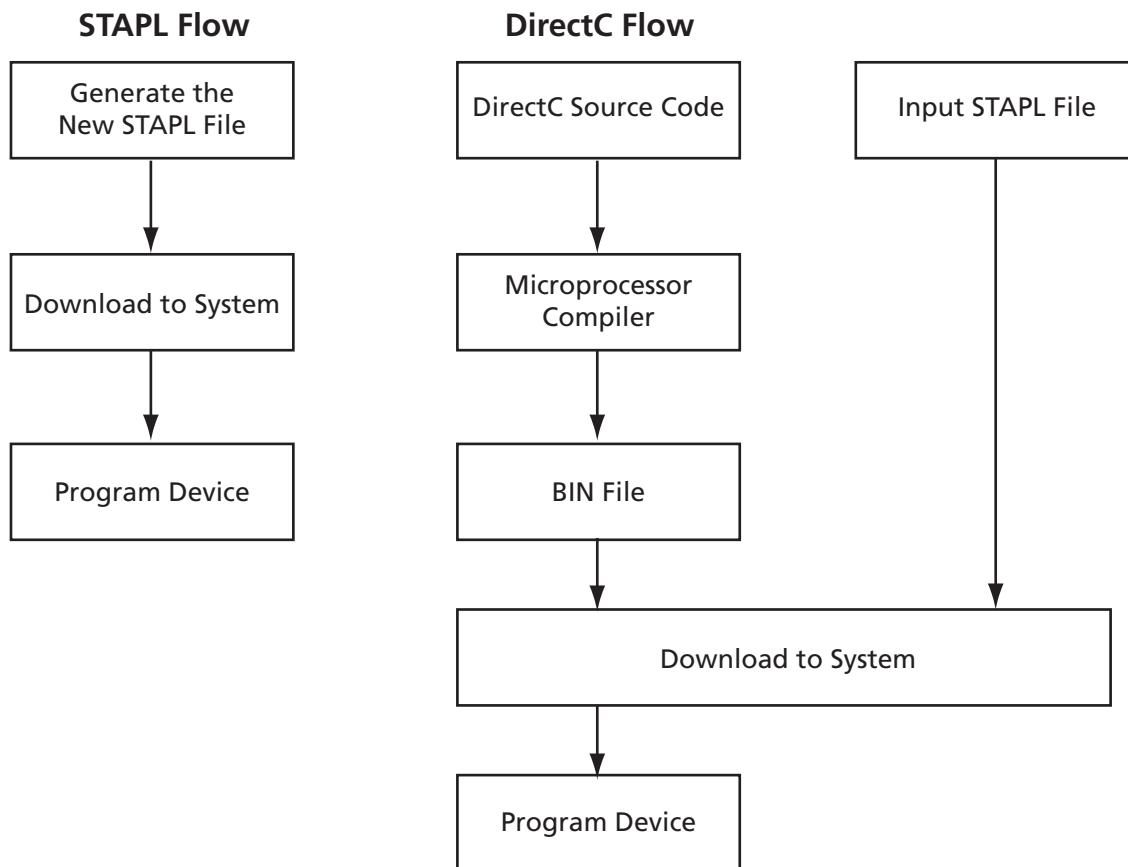

Figure 16-4 • STAPL vs. DirectC

Remote Upgrade via TCP/IP

Transmission Control Protocol (TCP) provides a reliable bitstream transfer service between two endpoints on a network. TCP depends on Internet Protocol (IP) to move packets around the network on its behalf. TCP protects against data loss, data corruption, packet reordering, and data duplication by adding checksums and sequence numbers to transmitted data and, on the receiving side, sending back packets and acknowledging the receipt of data.

The system containing the low-power flash device can be assigned an IP address when deployed in the field. When the device requires an update (core or FlashROM), the programming instructions along with the new programming data (AES-encrypted cipher text) can be sent over the Internet to the target system via the TCP/IP protocol. Once the MCU receives the instruction and data, it can proceed with the FPGA update. Low-power flash devices support Message Authentication Code (MAC), which can be used to validate data for the target device. More details are given in the "Message Authentication Code (MAC) Validation/Authentication" section on page 16-6.

Hardware Requirement

To facilitate the programming of the low-power flash families, the system must have a microprocessor (with access to the device JTAG pins) to process the programming algorithm, memory to store the programming algorithm, programming data, and the necessary programming voltage. Refer to the relevant datasheet for programming voltages.

Security

Read-Back Prevention

The low-power flash devices are designed with security in mind. Even without any security measures (such as FlashLock with AES), it is not possible to read back the programming data from a programmed device. Upon programming completion, the programming algorithm will reload the programming data into the device. The device will then use built-in circuitry to determine if it was programmed correctly.

As an additional security measure, the devices are equipped with AES decryption. AES works in two steps. The first step is to program a key into the devices in a secure or trusted programming center (such as Actel In-House Programming (IHP) center). The second step is to encrypt any programming files with the same encryption key. The encrypted programming file will only work with the devices that have the same key. The AES used in the low-power flash families is the 128-bit AES decryption engine (Rijndael algorithm).

Message Authentication Code (MAC) Validation/Authentication

As part of the AES decryption flow, the devices are equipped with a MAC validation/authentication system. MAC is an authentication tag, also called a checksum, derived by applying an on-chip authentication scheme to a STAPL file as it is loaded into the FPGA. MACs are computed and verified with the same key so they can only be verified by the intended recipient. When the MCU system receives the AES-encrypted programming data (cipher text), it can validate the data by loading it into the FPGA and performing a MAC verification prior to loading the data, via a second programming pass, into the FPGA core cells. This prevents erroneous or corrupt data from getting into the FPGA.

Low-power flash devices with AES and MAC are superior to devices with only DES or 3DES encryption. Because the MAC verifies the correctness of the data, the FPGA is protected from erroneous loading of invalid programming data that could damage a device (Figure 16-5 on page 16-7).

The AES with MAC enables field updates over public networks without fear of having the design stolen. An encrypted programming file can only work on devices with the correct key, rendering

any stolen files useless to the thief. To learn more about the low-power flash devices' security features, refer to *Security in Low-Power Flash Devices*.

Figure 16-5 • ProASIC3 Device Encryption Flow

Conclusion

The Actel Fusion, IGLOO, and ProASIC3 FPGAs are ideal for applications that require field upgrades. The single-chip devices save board space by eliminating the need for EEPROM. The built-in AES with MAC enables transmission of programming data over any network without fear of design theft. Fusion, IGLOO, and ProASIC3 FPGAs are IEEE 1532-compliant and support STAPL, making the target programming software easy to implement.

Boundary Scan and UJTAG

17 – Boundary Scan in Low-Power Flash Devices

Boundary Scan

Low-power flash devices are compatible with IEEE Standard 1149.1, which defines a hardware architecture and the set of mechanisms for boundary scan testing. JTAG operations are used during boundary scan testing.

The basic boundary scan logic circuit is composed of the TAP controller, test data registers, and instruction register (Figure 17-2 on page 17-4).

Low-power flash devices support three types of test data registers: bypass, device identification, and boundary scan. The bypass register is selected when no other register needs to be accessed in a device. This speeds up test data transfer to other devices in a test data path. The 32-bit device identification register is a shift register with four fields (LSB, ID number, part number, and version). The boundary scan register observes and controls the state of each I/O pin. Each I/O cell has three boundary scan register cells, each with serial-in, serial-out, parallel-in, and parallel-out pins.

TAP Controller State Machine

The TAP controller is a 4-bit state machine (16 states) that operates as shown in Figure 17-1.

The 1s and 0s represent the values that must be present on TMS at a rising edge of TCK for the given state transition to occur. IR and DR indicate that the instruction register or the data register is operating in that state.

The TAP controller receives two control inputs (TMS and TCK) and generates control and clock signals for the rest of the test logic architecture. On power-up, the TAP controller enters the Test-Logic-Reset state. To guarantee a reset of the controller from any of the possible states, TMS must remain HIGH for five TCK cycles. The TRST pin can also be used to asynchronously place the TAP controller in the Test-Logic-Reset state.

Figure 17-1 • TAP Controller State Machine

Actel's Flash Devices Support the JTAG Feature

The flash-based FPGAs listed in [Table 17-1](#) support the JTAG feature and the functions described in this document.

Table 17-1 • Flash-Based FPGAs

Series	Family*	Description

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 17-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 17-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Boundary Scan Support in Low-Power Devices

The information in this document applies to all Fusion, IGLOO, and ProASIC3 devices. For IGLOO, IGLOO PLUS, and ProASIC3L devices, the Flash*Freeze pin must be deasserted for successful boundary scan operations. Devices cannot enter JTAG mode directly from Flash*Freeze mode.

Boundary Scan Opcodes

Low-power flash devices support all mandatory IEEE 1149.1 instructions (EXTEST, SAMPLE/PRELOAD, and BYPASS) and the optional IDCODE instruction (Table 17-2).

Table 17-2 • Boundary Scan Opcodes

	Hex Opcode
EXTEST	00
HIGHZ	07
USERCODE	0E
SAMPLE/PRELOAD	01
IDCODE	0F
CLAMP	05
BYPASS	FF

Boundary Scan Chain

The serial pins are used to serially connect all the boundary scan register cells in a device into a boundary scan register chain (Figure 17-2 on page 17-4), which starts at the TDI pin and ends at the TDO pin. The parallel ports are connected to the internal core logic I/O tile and the input, output, and control ports of an I/O buffer to capture and load data into the register to control or observe the logic state of each I/O.

Each test section is accessed through the TAP, which has five associated pins: TCK (test clock input), TDI, TDO (test data input and output), TMS (test mode selector), and TRST (test reset input). TMS, TDI, and TRST are equipped with pull-up resistors to ensure proper operation when no input data is supplied to them. These pins are dedicated for boundary scan test usage. Refer to the "JTAG Pins" description in *Pin Descriptions* for pull-up/down recommendations for TDO and TCK pins.

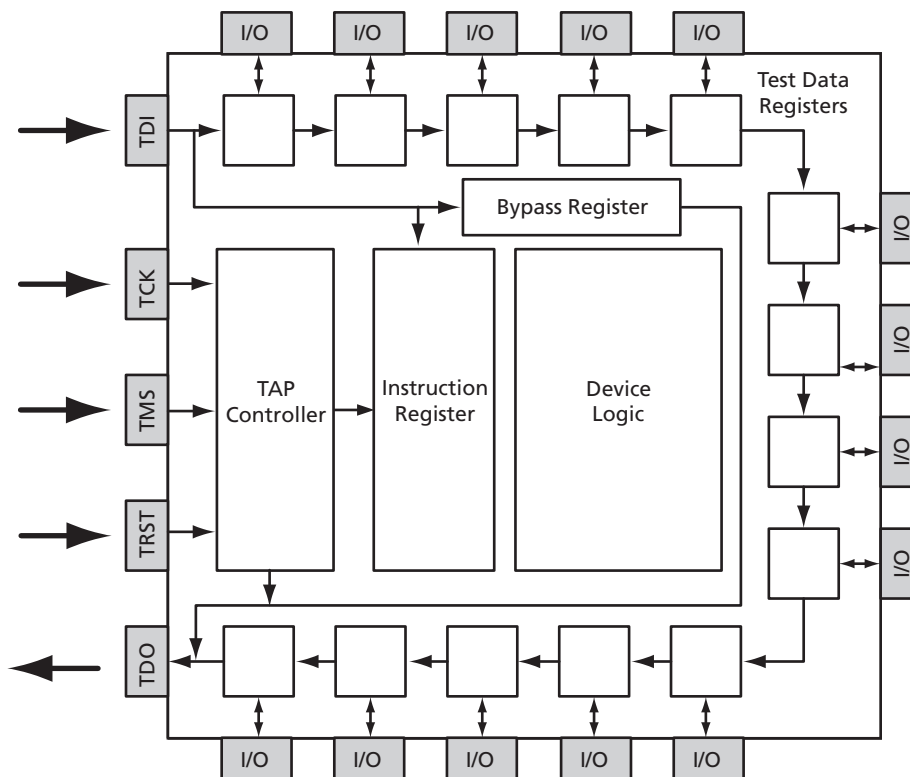

Figure 17-2 • Boundary Scan Chain

Board-Level Recommendations

Table 17-3 gives pull-down recommendations for the TRST and TCK pins.

Table 17-3 • TRST and TCK Pull-Down Recommendations

V_{JTAG}	Tie-Off Resistance*
V_{JTAG} at 3.3 V	200 Ω to 1 k Ω
V_{JTAG} at 2.5 V	200 Ω to 1 k Ω
V_{JTAG} at 1.8 V	500 Ω to 1 k Ω
V_{JTAG} at 1.5 V	500 Ω to 1 k Ω

* Equivalent parallel resistance if more than one device is on JTAG chain (Figure 17-3)

Note: TCK is correctly wired with an equivalent tie-off resistance of 500 Ω, which satisfies the table for V_{JTAG} of 1.5 V. The resistor values for TRST are not appropriate in this case, as the tie-off resistance of 375 Ω is below the recommended minimum for $V_{JTAG} = 1.5$ V, but would be appropriate for a V_{JTAG} setting of 2.5 V or 3.3 V.

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 17-1 · Flash-Based FPGAs .	17-2
v1.2 (June 2008)	The " Boundary Scan Support in Low-Power Devices " section was revised to include new families and make the information more concise.	17-3
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 17-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> • ProASIC3L was updated to include 1.5 V. • The number of PLLs for ProASIC3E was changed from five to six. 	17-2
v1.0 (January 2008)	The chapter was updated to include the IGLOO PLUS family and information regarding 15 k gate devices.	N/A
	The " IGLOO Terminology " section and " ProASIC3 Terminology " section are new.	17-2

18 – UJTAG Applications in Actel’s Low-Power Flash Devices

Introduction

In Fusion, IGLOO,® and ProASIC®3 devices, there is bidirectional access from the JTAG port to the core VersaTiles during normal operation of the device (Figure 18-1). User JTAG (UJTAG) is the ability for the design to use the JTAG ports for access to the device for updates, etc. While regular JTAG is used, the UJTAG tiles, located at the southeast area of the die, are directly connected to the JTAG Test Access Port (TAP) Controller in normal operating mode. As a result, all the functional blocks of the device, such as Clock Conditioning Circuits (CCCs) with PLLs, SRAM blocks, embedded FlashROM, flash memory blocks, and I/O tiles, can be reached via the JTAG ports. The UJTAG functionality is available by instantiating the UJTAG macro directly in the source code of a design. Access to the FPGA core VersaTiles from the JTAG ports enables users to implement different applications using the TAP Controller (JTAG port). This document introduces the UJTAG tile functionality and discusses a few application examples. However, the possible applications are not limited to what is presented in this document. UJTAG can serve different purposes in many designs as an elementary or auxiliary part of the design. For detailed usage information, refer to *Boundary Scan in Low-Power Flash Devices*.

Figure 18-1 • Block Diagram of Using UJTAG to Read FlashROM Contents

UJTAG Support in Flash-Based Devices

The flash-based FPGAs listed in [Table 18-1](#) support the UJTAG feature and the functions described in this document.

Table 18-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed-signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 18-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 18-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

UJTAG Macro

The UJTAG tiles can be instantiated in a design using the UJTAG macro from the Fusion, IGLOO, or ProASIC3 macro library. Note that "UJTAG" is a reserved name and cannot be used for any other user-defined blocks. A block symbol of the UJTAG tile macro is presented in [Figure 18-2](#). In this figure, the ports on the left side of the block are connected to the JTAG TAP Controller, and the right-side ports are accessible by the FPGA core VersaTiles. The TDI, TMS, TDO, TCK, and TRST ports of UJTAG are only provided for design simulation purposes and should be treated as external signals in the design netlist. However, these ports must NOT be connected to any I/O buffer in the netlist. [Figure 18-3 on page 18-4](#) illustrates the correct connection of the UJTAG macro to the user design netlist. Actel Designer software will automatically connect these ports to the TAP during place-and-route. [Table 18-2](#) gives the port descriptions for the rest of the UJTAG ports:

Table 18-2 • UJTAG Port Descriptions

Port	Description
UIREG [7:0]	This 8-bit bus carries the contents of the JTAG Instruction Register of each device. Instruction Register values 16 to 127 are not reserved and can be employed as user-defined instructions.
URSTB	URSTB is an active-low signal and will be asserted when the TAP Controller is in Test-Logic-Reset mode. URSTB is asserted at power-up, and a power-on reset signal resets the TAP Controller. URSTB will stay asserted until an external TAP access changes the TAP Controller state.
UTDI	This port is directly connected to the TAP's TDI signal.
UTDO	This port is the user TDO output. Inputs to the UTDO port are sent to the TAP TDO output MUX when the IR address is in user range.
UDRSH	Active-high signal enabled in the ShiftDR TAP state
UDRCAP	Active-high signal enabled in the CaptureDR TAP state
UDRCK	This port is directly connected to the TAP's TCK signal.
UDRUPD	Active-high signal enabled in the UpdateDR TAP state

Figure 18-2 • UJTAG Tile Block Symbol

Note: Do not connect JTAG pins (TDO, TDI, TMS, TCK, or TRST) to I/Os in the design.

Figure 18-3 • Connectivity Method of UJTAG Macro

UJTAG Operation

There are a few basic functions of the UJTAG macro that users must understand before designing with it. The most important fundamental concept of the UJTAG design is its connection with the TAP Controller state machine.

TAP Controller State Machine

The 16 states of the TAP Controller state machine are shown in [Figure 18-4 on page 18-5](#). The 1s and 0s, shown adjacent to the state transitions, represent the TMS values that must be present at the time of a rising TCK edge for a state transition to occur. In the states that include the letters "IR," the instruction register operates; in the states that contain the letters "DR," the test data register operates. The TAP Controller receives two control inputs, TMS and TCK, and generates control and clock signals for the rest of the test logic.

On power-up (or the assertion of TRST), the TAP Controller enters the Test-Logic-Reset state. To reset the controller from any other state, TMS must be held HIGH for at least five TCK cycles. After reset, the TAP state changes at the rising edge of TCK, based on the value of TMS.

Figure 18-4 • TAP Controller State Diagram

UJTAG Port Usage

UIREG[7:0] hold the contents of the JTAG instruction register. The UIREG vector value is updated when the TAP Controller state machine enters the Update_IR state. Instructions 16 to 127 are user-defined and can be employed to encode multiple applications and commands within an application. Loading new instructions into the UIREG vector requires users to send appropriate logic to TMS to put the TAP Controller in a full IR cycle starting from the Select IR_Scan state and ending with the Update_IR state.

UTDI, UTDO, and UDRCK are directly connected to the JTAG TDI, TDO, and TCK ports, respectively. The TDI input can be used to provide either data (TAP Controller in the Shift_DR state) or the new contents of the instruction register (TAP Controller in the Shift_IR state).

UDRSH, UDRUPD, and UDRCAP are HIGH when the TAP Controller state machine is in the Shift_DR, Update_DR, and Capture_DR states, respectively. Therefore, they act as flags to indicate the stages of the data shift process. These flags are useful for applications in which blocks of data are shifted into the design from JTAG pins. For example, an active UDRSH can indicate that UTDI contains the data bitstream, and UDRUPD is a candidate for the end-of-data-stream flag.

As mentioned earlier, users should not connect the TDI, TDO, TCK, TMS, and TRST ports of the UJTAG macro to any port or net of the design netlist. The Designer software will automatically handle the port connection.

Typical UJTAG Applications

Bidirectional access to the JTAG port from VersaTiles—without putting the device into test mode—creates flexibility to implement many different applications. This section describes a few of these. All are based on importing/exporting data through the UJTAG tiles.

Clock Conditioning Circuitry—Dynamic Reconfiguration

In low-power flash devices, CCCs, which include PLLs, can be configured dynamically through either an 81-bit embedded shift register or static flash programming switches. These 81 bits control all the characteristics of the CCC: routing MUX architectures, delay values, divider values, etc. [Table 18-3](#) lists the 81 configuration bits in the CCC.

Table 18-3 • Configuration Bits of Fusion, IGLOO, and ProASIC3 CCC Blocks

Bit Number(s)	Control Function
80	RESET ENABLE
79	DYNCSEL
78	DYNBSEL
77	DYNASEL
<76:74>	VCOSEL [2:0]
73	STATCSEL
72	STATBSEL
71	STATASEL
<70:66>	DLYC [4:0]
<65:61>	DLYB [4:0]
<60:56>	DLYGLC [4:0]
<55:51>	DLYGLB [4:0]
<50:46>	DLYGLA [4:0]
45	XDLYSEL
<44:40>	FBDLY [4:0]
<39:38>	FBSEL
<37:35>	OCMUX [2:0]
<34:32>	OBMUX [2:0]
<31:29>	OAMUX [2:0]
<28:24>	OCDIV [4:0]
<23:19>	OBDIV [4:0]
<18:14>	OADIV [4:0]
<13:7>	FBDIV [6:0]
<6:0>	FINDIV [6:0]

The embedded 81-bit shift register (for the dynamic configuration of the CCC) is accessible to the VersaTiles, which, in turn, have access to the UJTAG tiles. Therefore, the CCC configuration shift register can receive and load the new configuration data stream from JTAG.

Dynamic reconfiguration eliminates the need to reprogram the device when reconfiguration of the CCC functional blocks is needed. The CCC configuration can be modified while the device continues to operate. Employing the UJTAG core requires the user to design a module to provide the configuration data and control the CCC configuration shift register. In essence, this is a user-designed TAP Controller requiring chip resources.

Similar reconfiguration capability exists in the Actel ProASIC^{PLUS}® family. The only difference is the number of shift register bits controlling the CCC (27 in ProASIC^{PLUS} and 81 in IGLOO, ProASIC3, and Fusion).

Fine Tuning

In some applications, design constants or parameters need to be modified after programming the original design. The tuning process can be done using the UJTAG tile without reprogramming the device with new values. If the parameters or constants of a design are stored in distributed registers or embedded SRAM blocks, the new values can be shifted onto the JTAG TAP Controller pins, replacing the old values. The UJTAG tile is used as the "bridge" for data transfer between the JTAG pins and the FPGA VersaTiles or SRAM logic. Figure 18-5 shows a flow chart example for fine-tuning application steps using the UJTAG tile.

In Figure 18-5, the TMS signal sets the TAP Controller state machine to the appropriate states. The flow mainly consists of two steps: a) shifting the defined instruction and b) shifting the new data. If the target parameter is constantly used in the design, the new data can be shifted into a temporary shift register from UTDI. The UDRSH output of UJTAG can be used as a shift-enable signal, and UDRCK is the shift clock to the shift register. Once the shift process is completed and the TAP Controller state is moved to the Update_DR state, the UDRUPD output of the UJTAG can latch the new parameter value from the temporary register into a permanent location. This avoids any interruption or malfunctioning during the serial shift of the new value.

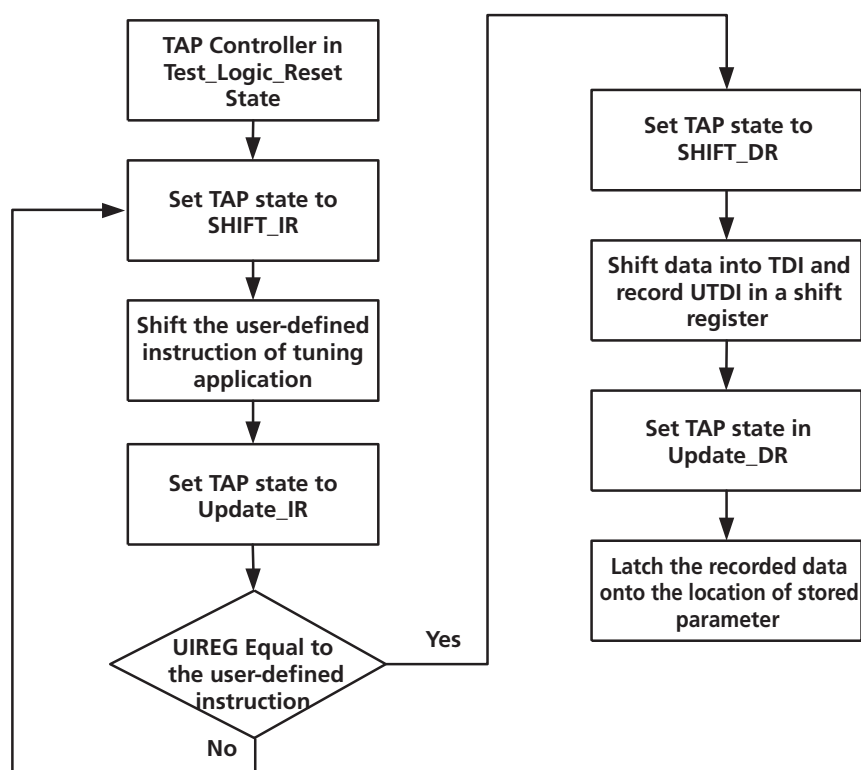

Figure 18-5 • Flow Chart Example of Fine-Tuning an Application Using UJTAG

Silicon Testing and Debugging

In many applications, the design needs to be tested, debugged, and verified on real silicon or in the final embedded application. To debug and test the functionality of designs, users may need to monitor some internal logic (or nets) during device operation. The approach of adding design test pins to monitor the critical internal signals has many disadvantages, such as limiting the number of user I/Os. Furthermore, adding external I/Os for test purposes may require additional or dedicated board area for testing and debugging.

The UJTAG tiles of low-power flash devices offer a flexible and cost-effective solution for silicon test and debug applications. In this solution, the signals under test are shifted out to the TDO pin of the TAP Controller. The main advantage is that all the test signals are monitored from the TDO pin; no pins or additional board-level resources are required. Figure 18-6 illustrates this technique. Multiple test nets are brought into an internal MUX architecture. The selection of the MUX is done using the contents of the TAP Controller instruction register, where individual instructions (values from 16 to 127) correspond to different signals under test. The selected test signal can be synchronized with the rising or falling edge of TCK (optional) and sent out to UTDO to drive the TDO output of JTAG.

The test and debug procedure is not limited to the example in Figure 18-5 on page 18-7. Users can customize the debug and test interface to make it appropriate for their applications. For example, multiple test signals can be registered and then sent out through UTDO, each at a different edge of TCK. In other words, n signals are sampled with an F_{TCK} / n sampling rate. The bandwidth of the information sent out to TDO is always proportional to the frequency of TCK.

Figure 18-6 • UJTAG Usage Example in Test and Debug Applications

SRAM Initialization

Users can also initialize embedded SRAMs of the low-power flash devices. The initialization of the embedded SRAM blocks of the design can be done using UJTAG tiles, where the initialization data is imported using the TAP Controller. Similar functionality is available in ProASIC^{PLUS} devices using JTAG. The guidelines for implementation and design examples are given in the [RAM Initialization and ROM Emulation in ProASIC^{PLUS} Devices](#) application note.

SRAMs are volatile by nature; data is lost in the absence of power. Therefore, the initialization process should be done at each power-up if necessary.

FlashROM Read-Back Using JTAG

The low-power flash architecture contains a dedicated nonvolatile FlashROM block, which is formatted into eight 128-bit pages. For more information on FlashROM, refer to *FlashROM in Actel's Low-Power Flash Devices*. The contents of FlashROM are available to the VersaTiles during normal operation through a read operation. As a result, the UJTAG macro can be used to provide the FlashROM contents to the JTAG port during normal operation. Figure 18-7 illustrates a simple block diagram of using UJTAG to read the contents of FlashROM during normal operation.

The FlashROM read address can be provided from outside the FPGA through the TDI input or can be generated internally using the core logic. In either case, data serialization logic is required (Figure 18-7) and should be designed using the VersaTile core logic. FlashROM contents are read asynchronously in parallel from the flash memory and shifted out in a synchronous serial format to TDO. Shifting the serial data out of the serialization block should be performed while the TAP is in UDRSH mode. The coordination between TCK and the data shift procedure can be done using the TAP state machine by monitoring UDRSH, UDRCAP, and UDRUPD.

Figure 18-7 • Block Diagram of Using UJTAG to Read FlashROM Contents

Conclusion

Actel low-power flash FPGAs offer many unique advantages, such as security, nonvolatility, reprogrammability, and low power—all in a single chip. In addition, Fusion, IGLOO, and ProASIC3 devices provide access to the JTAG port from core VersaTiles while the device is in normal operating mode. A wide range of available user-defined JTAG opcodes allows users to implement various types of applications, exploiting this feature of these devices. The connection between the JTAG port and core tiles is implemented through an embedded and hardwired UJTAG tile. A UJTAG tile can be instantiated in designs using the UJTAG library cell. This document presents multiple examples of UJTAG applications, such as dynamic reconfiguration, silicon test and debug, fine-tuning of the design, and RAM initialization. Each of these applications offers many useful advantages.

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.4)	Page
v1.3 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to Table 18-1 · Flash-Based FPGAs .	18-2
v1.2 (June 2008)	The " UJTAG Support in Flash-Based Devices " section was revised to include new families and make the information more concise.	18-2
	The title of Table 18-3 · Configuration Bits of Fusion, IGLOO, and ProASIC3 CCC Blocks was revised to include Fusion.	18-6
v1.1 (March 2008)	The following changes were made to the family descriptions in Table 18-1 · Flash-Based FPGAs : <ul style="list-style-type: none"> ProASIC3L was updated to include 1.5 V. The number of PLLs for ProASIC3E was changed from five to six. 	18-2
v1.0 (January 2008)	The chapter was updated to include the IGLOO PLUS family and information regarding 15 k gate devices.	N/A
	The " IGLOO Terminology " section and " ProASIC3 Terminology " section are new.	18-2

Board-Level Requirements

19 – Power-Up/-Down Behavior of Low-Power Flash Devices

Introduction

Actel's low-power flash devices are flash-based FPGAs manufactured on a 0.13 μm process node. These devices offer a single-chip, reprogrammable solution and support Level 0 live at power-up (LAPU) due to their nonvolatile architecture.

Actel's low-power flash FPGA families are optimized for logic area, I/O features, and performance. IGLOO® devices are optimized for power, making them the industry's lowest power programmable solution. IGLOO PLUS FPGAs offer enhanced I/O features beyond those of the IGLOO ultra-low-power solution for I/O-intensive low-power applications. IGLOO nano devices are the industry's lowest-power cost-effective solution. ProASIC3®L FPGAs balance low power with high performance. The ProASIC3 family is Actel's high-performance flash FPGA solution. ProASIC3 nano devices offer the lowest-cost solution with enhanced I/O capabilities.

Actel's low-power flash devices exhibit very low transient current on each power supply during power-up. The peak value of the transient current depends on the device size, temperature, voltage levels, and power-up sequence.

The following devices can have inputs driven in while the device is not powered:

- IGLOO (AGL015 and AGL030)
- IGLOO nano (all devices)
- IGLOO PLUS (AGLP030, AGLP060, AGLP125)
- IGLOOe (AGLE600, AGLE3000)
- ProASIC3L (A3PE3000L)
- ProASIC3 (A3P015, A3P030)
- ProASIC3 nano (all devices)
- ProASIC3E (A3PE600, A3PE1500, A3PE3000)
- Military ProASIC3EL (A3PE600L, A3PE3000L, but not A3P1000)
- RT ProASIC3 (RT3PE600L, RT3PE3000L)

The driven I/Os do not pull up power planes, and the current draw is limited to very small leakage current, making them suitable for applications that require cold-sparing. These devices are hot-swappable, meaning they can be inserted in a live power system.¹

1. For more details on the levels of hot-swap compatibility in Actel's low-power flash devices, refer to the "Hot-Swap Support" section in the I/O Structures chapter of the handbook for the device you are using.

Actel's Flash Devices Support Power-Up Behavior

The flash FPGAs listed in [Table 19-1](#) support power-up behavior and the functions described in this document.

Table 19-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low-power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low-power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in [Table 19-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in [Table 19-1](#). Where the information applies to only one product line or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the [Industry's Lowest Power FPGAs Portfolio](#).

Power-Up/-Down Sequence and Transient Current

Actel's low-power flash devices use the following main voltage pins during normal operation:²

- V_{CCPLX}
- V_{JTAG}
- V_{CC} : Voltage supply to the FPGA core
 - V_{CC} is $1.5\text{ V} \pm 0.075\text{ V}$ for IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3 devices operating at 1.5 V.
 - V_{CC} is $1.2\text{ V} \pm 0.06\text{ V}$ for IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3L devices operating at 1.2 V.
 - V5 devices will require a 1.5 V V_{CC} supply, whereas V2 devices can utilize either a 1.2 V or 1.5 V V_{CC} .
- $V_{CCI}Bx$: Supply voltage to the bank's I/O output buffers and I/O logic. Bx is the I/O bank number.
- $VMVx$: Quiet supply voltage to the input buffers of each I/O bank. x is the bank number. (Note: IGLOO nano, IGLOO PLUS, and ProASIC3 nano devices do not have $VMVx$ supply pins.)

The I/O bank VMV pin must be tied to the V_{CCI} pin within the same bank. Therefore, the supplies that need to be powered up/down during normal operation are V_{CC} and V_{CCI} . These power supplies can be powered up/down in any sequence during normal operation of IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, ProASIC3, and ProASIC3 nano FPGAs. During power-up, I/Os in each bank will remain tristated until the last supply (either $V_{CCI}Bx$ or V_{CC}) reaches its functional activation voltage. Similarly, during power-down, I/Os of each bank are tristated once the first supply reaches its brownout deactivation voltage.

Although Actel's low-power flash devices have no power-up or power-down sequencing requirements, Actel identifies the following power conditions that will result in higher than normal transient current. Use this information to help maximize power savings:

Actel recommends tying V_{CCPLX} to V_{CC} and using proper filtering circuits to decouple V_{CC} noise from the PLL.

- a. If V_{CCPLX} is powered up before V_{CC} , a static current of up to 5 mA (typical) per PLL may be measured on V_{CCPLX} .
 - i. The current vanishes as soon as V_{CC} reaches the V_{CCPLX} voltage level.
 - ii. The same current is observed at power-down (V_{CC} before V_{CCPLX}).
- b. If V_{CCPLX} is powered up simultaneously or after V_{CC} :
 - i. Actel's low-power flash devices exhibit very low transient current on V_{CC} . For ProASIC3 devices, the maximum transient current on V_{CC} does not exceed the maximum standby current specified in the device datasheet.

The source of transient current, also known as inrush current, varies depending on the FPGA technology. Due to their volatile technology, the internal registers in SRAM FPGAs must be initialized before configuration can start. This initialization is the source of significant inrush current in SRAM FPGAs during power-up. Due to the nonvolatile nature of flash technology, low-power flash devices do not require any initialization at power-up, and there is very little or no crossbar current through PMOS and NMOS devices. Therefore, the transient current at power-up is significantly less than for SRAM FPGAs. [Figure 19-1 on page 19-4](#) illustrates the types of power consumption by SRAM FPGAs compared to Actel's antifuse and flash FPGAs.

2. For more information on Actel FPGA voltage supplies, refer to the appropriate datasheet located at <http://www.actel.com/techdocs/ids>.

Figure 19-1 • Types of Power Consumption in SRAM FPGAs and Actel Nonvolatile FPGAs

Transient Current on V_{CC}

The characterization of the transient current on V_{CC} is performed on nearly all devices within the IGLOO, ProASIC3L, and ProASIC3 families. A sample size of five units is used from each device family member. All the device I/Os are internally pulled down while the transient current measurements are performed. For ProASIC3 devices, the measurements at typical conditions show that the maximum transient current on V_{CC} , when the power supply is powered at ramp-rates ranging from 15 V/ms to 0.15 V/ms, does not exceed the maximum standby current specified in the device datasheets. Refer to *ProASIC3 DC and Switching Characteristics* and *ProASIC3E DC and Switching Characteristics* for more information.

Similarly, IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3L devices exhibit very low transient current on V_{CC} . The transient current does not exceed the typical operating current of the device while in active mode. For example, the characterization of AGL600-FG256 V2 and V5 devices has shown that the transient current on V_{CC} is typically in the range of 1–5 mA.

Transient Current on V_{CCI}

The characterization of the transient current on V_{CCI} is performed on devices within the IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3, ProASIC3 nano, and ProASIC3L groups of devices, similarly to V_{CC} transient current measurements. For ProASIC3 devices, the measurements at typical conditions show that the maximum transient current on V_{CCI} , when the power supply is powered at ramp-rates ranging from 33 V/ms to 0.33 V/ms, does not exceed the maximum standby current specified in the device datasheet. Refer to *ProASIC3 DC and Switching Characteristics* and *ProASIC3E DC and Switching Characteristics* for more information.

Similarly, IGLOO, IGLOO PLUS, and ProASIC3L devices exhibit very low transient current on V_{CCI} . The transient current does not exceed the typical operating current of the device while in active mode. For example, the characterization of AGL600-FG256 V2 and V5 devices has shown that the transient current on V_{CCI} is typically in the range of 1–2 mA.

I/O Behavior at Power-Up/-Down

This section discusses the behavior of device I/Os, used and unused, during power-up/-down of V_{CC} and V_{CCI} . As mentioned earlier, $VMVx$ and $V_{CCI}Bx$ are tied together, and therefore, inputs and outputs are powered up/down at the same time.

I/O State during Power-Up/-Down

This section discusses the characteristics of I/O behavior during device power-up and power-down. Before the start of power-up, all I/Os are in tristate mode. The I/Os will remain tristated during power-up until the last voltage supply (V_{CC} or V_{CCI}) is powered to its functional level (power supply functional levels are discussed in the "Power-Up to Functional Time" section on page 19-6). After the last supply reaches the functional level, the outputs will exit the tristate mode and drive the logic at the input of the output buffer. Similarly, the input buffers will pass the external logic into the FPGA fabric once the last supply reaches the functional level. The behavior of user I/Os is independent of the V_{CC} and V_{CCI} sequence or the state of other voltage supplies of the FPGA (V_{PUMP} and V_{JTAG}). Figure 19-2 shows the output buffer driving HIGH and its behavior during power-up with 10 k Ω external pull-down. In Figure 19-2, V_{CC} is powered first, and V_{CCI} is powered 5 ms after V_{CC} . Figure 19-3 on page 19-6 shows the state of the I/O when V_{CCI} is powered about 5 ms before V_{CC} . In the circuitry shown in Figure 19-3 on page 19-6, the output is externally pulled down.

During power-down, device I/Os become tristated once the first power supply (V_{CC} or V_{CCI}) drops below its brownout voltage level. The I/O behavior during power-down is also independent of voltage supply sequencing.

Figure 19-2 • I/O State when V_{CC} Is Powered before V_{CCI}

Figure 19-3 • I/O State when V_{CCI} Is Powered before V_{CC}

Power-Up to Functional Time

At power-up, device I/Os exit the tristate mode and become functional once the last voltage supply in the power-up sequence (V_{CCI} or V_{CC}) reaches its functional activation level. The power-up-to-functional time is the time it takes for the last supply to power up from zero to its functional level. Note that the functional level of the power supply during power-up may vary slightly within the specification at different ramp-rates. Refer to Table 19-2 for the functional level of the voltage supplies at power-up.

Typical I/O behavior during power-up-to-functional time is illustrated in Figure 19-2 on page 19-5 and Figure 19-3.

Table 19-2 • Power-Up Functional Activation Levels for V_{CC} and V_{CCI}

Device	V_{CC} Functional Activation Level (V)	V_{CCI} Functional Activation Level (V)
ProASIC3, ProASIC3 nano, IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3L devices running at $V_{CC} = 1.5 V^*$	$0.85 V \pm 0.25 V$	$0.9 V \pm 0.3 V$
IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3L devices running at $V_{CC} = 1.2 V^*$	$0.85 V \pm 0.2 V$	$0.9 V \pm 0.15 V$

Note: *V5 devices will require a 1.5 V V_{CC} supply, whereas V2 devices can utilize either a 1.2 V or 1.5 V V_{CC} .

Actel's low-power flash devices meet Level 0 LAPU; that is, they can be functional prior to V_{CC} reaching the regulated voltage required. This important advantage distinguishes low-power flash devices from their SRAM-based counterparts. SRAM-based FPGAs, due to their volatile technology, require hundreds of milliseconds after power-up to configure the design bitstream before they become functional. Refer to Figure 19-4 on page 19-7 and Figure 19-5 on page 19-8 for more information.

Figure 19-4 • I/O State as a Function of V_{CCI} and V_{CC} Voltage Levels for IGLOO V5, IGLOO nano V5, IGLOO PLUS V5, ProASIC3L, and ProASIC3 Devices Running at $V_{CC} = 1.5\text{ V} \pm 0.075\text{ V}$

Brownout Voltage

Brownout is a condition in which the voltage supplies are lower than normal, causing the device to malfunction as a result of insufficient power. In general, Actel does not guarantee the functionality of the design inside the flash FPGA if voltage supplies are below their minimum recommended operating condition. Actel has performed measurements to characterize the brownout levels of FPGA power supplies. Refer to [Table 19-3](#) for device-specific brownout deactivation levels. For the purpose of characterization, a direct path from the device input to output is monitored while voltage supplies are lowered gradually. The brownout point is defined as the voltage level at which the output stops following the input. Characterization tests performed on several IGLOO, ProASIC3L, and ProASIC3 devices in typical operating conditions showed the brownout voltage levels to be within the specification.

During device power-down, the device I/Os become tristated once the first supply in the power-down sequence drops below its brownout deactivation voltage.

Table 19-3 • Brownout Deactivation Levels for V_{CC} and V_{CCI}

Devices	V_{CC} Brownout Deactivation Level (V)	V_{CCI} Brownout Deactivation Level (V)
ProASIC3, ProASIC3 nano, IGLOO, IGLOO nano, IGLOO PLUS and ProASIC3L devices running at $V_{CC} = 1.5$ V	0.75 V \pm 0.25 V	0.8 V \pm 0.3 V
IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3L devices running at $V_{CC} = 1.2$ V	0.75 V \pm 0.2 V	0.8 V \pm 0.15 V

PLL Behavior at Brownout Condition

When PLL power supply voltage and/or V_{CC} levels drop below the V_{CC} brownout levels mentioned above for 1.5 V and 1.2 V devices, the PLL output lock signal goes LOW and/or the output clock is lost. The following sections explain PLL behavior during and after the brownout condition.

V_{CCPLL} and V_{CC} Tied Together

In this condition, both V_{CC} and V_{CCPLL} drop below the 0.75 V (\pm 0.25 V or \pm 0.2 V) brownout level. During the brownout recovery, once V_{CCPLL} and V_{CC} reach the activation point (0.85 \pm 0.25 V or \pm 0.2 V) again, the PLL output lock signal may still remain LOW with the PLL output clock signal toggling. If this condition occurs, there are two ways to recover the PLL output lock signal:

1. Cycle the power supplies of the PLL (power off and on) by using the PLL POWERDOWN signal.
2. Turn off the input reference clock to the PLL and then turn it back on.

Only V_{CCPLL} Is at Brownout

In this case, only V_{CCPLL} drops below the 0.75 V (\pm 0.25 V or \pm 0.2 V) brownout level and the V_{CC} supply remains at nominal recommended operating voltage (1.5 V \pm 0.075 V for 1.5 V devices and 1.2 V \pm 0.06 V for 1.2 V devices). In this condition, the PLL behavior after brownout recovery is similar to initial power-up condition, and the PLL will regain lock automatically after V_{CCPLL} is ramped up above the activation level (0.85 \pm 0.25 V or \pm 0.2 V). No intervention is necessary in this case.

Only V_{CC} Is at Brownout

In this condition, V_{CC} drops below the 0.75 V (\pm 0.25 V or \pm 0.2 V) brownout level and V_{CCPLL} remains at nominal recommended operating voltage (1.5 V \pm 0.075 V for 1.5 V devices and 1.2 V \pm 0.06 V for 1.2 V devices). During the brownout recovery, once V_{CC} reaches the activation point again (0.85 \pm 0.25 V or \pm 0.2 V), the PLL output lock signal may still remain LOW with the PLL output clock signal toggling. If this condition occurs, there are two ways to recover the PLL output lock signal:

1. Cycle the power supplies of the PLL (power off and on) by using the PLL POWERDOWN signal.
2. Turn off the input reference clock to the PLL and then turn it back on.

It is important to note that Actel recommends using a monotonic power supply or voltage regulator to ensure proper power-up behavior.

Internal Pull-Up and Pull-Down

Low-power flash device I/Os are equipped with internal weak pull-up/down resistors that can be used by designers. If used, these internal pull-up/down resistors will be activated during power-up, once both V_{CC} and V_{CCI} are above their functional activation level. Similarly, during power-down, these internal pull-up/down resistors will turn off once the first supply voltage falls below its brownout deactivation level.

Cold-Sparing

In cold-sparing applications, voltage can be applied to device I/Os before and during power-up. Cold-sparing applications rely on three important characteristics of the device:

1. I/Os must be tristated before and during power-up.
2. Voltage applied to the I/Os must not power up any part of the device.
3. V_{CCI} should not exceed 3.6 V, per datasheet specifications.

As described in the "Power-Up to Functional Time" section on page 19-6, Actel's low-power flash I/Os are tristated before and during power-up until the last voltage supply (V_{CC} or V_{CCI}) is powered up past its functional level. Furthermore, applying voltage to the FPGA I/Os does not pull up V_{CC} or V_{CCI} and, therefore, does not partially power up the device. Table 19-4 includes the cold-sparing test results on A3PE600-PQ208 devices. In this test, leakage current on the device I/O and residual voltage on the power supply rails were measured while voltage was applied to the I/O before power-up.

Table 19-4 • Cold-Sparing Test Results for A3PE600 Devices

Device I/O	Residual Voltage (V)		Leakage Current
	V_{CC}	V_{CCI}	
Input	0	0.003	<1 μ A
Output	0	0.003	<1 μ A

V_{CCI} must not exceed 3.6 V, as stated in the datasheet specification. Therefore, ProASIC3E devices meet all three requirements stated earlier in this section and are suitable for cold-sparing applications.

The following devices and families support cold-sparing:

- IGLOO: AGL015 and AGL030
- All IGLOO nano
- All IGLOO PLUS
- All IGLOOe
- ProASIC3L: A3PE3000L
- ProASIC3: A3P015 and A3P030
- All ProASIC3 nano
- All ProASIC3E
- Military ProASIC3EL: A3PE600L and A3PE3000L
- RT ProASIC3: RT3PE600L and RT3PE3000L

The following devices and families do not support cold-sparing:

- IGLOO: AGL060, AGL125, AGL250, AGL600, AGL1000
- ProASIC3: A3P060, A3P125, A3P250, A3P400, A3P600, A3P1000
- ProASIC3L: A3P250L, A3P600L, A3P1000L
- Military ProASIC3: A3P1000

Hot-Swapping

Hot-swapping is the operation of hot insertion or hot removal of a card in a powered-up system. The I/Os need to be configured in hot-insertion mode if hot-swapping compliance is required. For more details on the levels of hot-swap compatibility in low-power flash devices, refer to the "Hot-Swap Support" section in the I/O Structures chapter of the handbook for the device you are using.

The following devices and families support hot-swapping:

- IGLOO: AGL015 and AGL030
- All IGLOO nano
- All IGLOO PLUS
- All IGLOOe
- ProASIC3L: A3PE3000L
- ProASIC3: A3P015 and A3P030
- All ProASIC3 nano
- All ProASIC3E
- Military ProASIC3EL: A3PE600L and A3PE3000L
- RT ProASIC3: RT3PE600L and RT3PE3000L

The following devices and families do not support hot-swapping:

- IGLOO: AGL060, AGL125, AGL250, AGL400, AGL600, AGL1000
- ProASIC3: A3P060, A3P125, A3P250, A3P400, A3P600, A3P1000
- ProASIC3L: A3P250L, A3P600L, A3P1000L
- Military ProASIC3: A3P1000

Conclusion

Actel's low-power flash FPGAs provide an excellent programmable logic solution for a broad range of applications. In addition to high performance, low cost, security, nonvolatility, and single chip, they are live at power-up (meet Level 0 of the LAPU classification) and offer clear and easy-to-use power-up/down characteristics. Unlike SRAM FPGAs, low-power flash devices do not require any specific power-up/down sequencing and have extremely low power-up inrush current in any power-up sequence. Actel low-power flash FPGAs also support both cold-sparing and hot-swapping for applications requiring these capabilities.

Part Number and Revision Date

This document was a previously published handbook chapter that only discussed ProASIC3/E (*Power-Up Behavior of ProASIC3/E Devices*, part number 51700094-021), and has now been updated to include data for IGLOO and ProASIC3L families.

Part Number 51700094-027-2

Revised December 2008

List of Changes

The following table lists critical changes that were made in the current version of the chapter.

Previous Version	Changes in Current Version (v1.2)	Page
v1.1 (October 2008)	IGLOO nano and ProASIC3 nano devices were added to the document as supported device types.	N/A
v1.0 (August 2008)	The "Introduction" section was updated to add Military ProASIC3EL and RT ProASIC3 devices to the list of devices that can have inputs driven in while the device is not powered.	19-1
	The "Actel's Flash Devices Support Power-Up Behavior" section was revised to include new families and make the information more concise.	19-2
	The "Cold-Sparing" section was revised to add Military ProASIC3/EL and RT ProASIC3 devices to the lists of devices with and without cold-sparing support.	19-10
	The "Hot-Swapping" section was revised to add Military ProASIC3/EL and RT ProASIC3 devices to the lists of devices with and without hot-swap support. AGL400 was added to the list of devices that do not support hot-swapping.	19-11
v1.3 (March 2008)	This document was revised, renamed, and assigned a new part number. It now includes data for the IGLOO and ProASIC3L families.	N/A
v1.2 (January 2008) 51700094-021-2	The "Handbook Documents" section was updated to include the three different I/O Structure handbook chapters.	19-12
v1.1 (January 2008) 51700094-021-1	The first sentence of the "PLL Behavior at Brownout Condition" section was updated to read, "When PLL power supply voltage and/or V _{CC} levels drop below the V _{CC} brownout levels (0.75 V ± 0.25 V), the PLL output lock signal goes low and/or the output clock is lost."	19-9
v1.0 (January 2008) 51700094-021-0	The "PLL Behavior at Brownout Condition" section was added.	19-9
